Software Development

• While there are many approaches to Software Development, they can generally be placed into 2 categories:
  • **Plan Driven** – following a version of the Waterfall Development Process
  • **Iterative Driven** – following a version of the Agile Development Process

• Plan Drive programs have an assumption of some reliable/realistic size metric, for example:
  • Source Lines of Code (SLOC)
  • Function Points
  • Use Cases, etc.
Software Development

• Iterative Drive programs, by nature, start with a less well-defined metric
  • Therefore, they may require alternative estimating approaches

• This briefing will focus on the challenges of estimating an iterative program using Agile software development

• In practical experience the terms iterative, incremental and agile may be used interchangably

While Incremental/Agile programs say they do not have development metrics, I have almost always found them in the development room
IID Programs’ Key Terms

• **IID** is an approach to building software in which the overall lifecycle is composed of iterations or sprints in sequence
  • Each Iteration is a self-contained mini project
  • It grew out of the increased application of Agile Development techniques

• In many defense programs, **increments** are 6 -12 months in length and each increment is composed of multiple **iterations/sprints** of 1-6 weeks

• Time-boxing is the practice of fixing the iteration or increment dates and not allowing it to change

• This approach is gaining favor in large federal programs
Each Iteration/Sprint is a Mini Project

• Each iteration/sprint includes production-quality programming, not just, for example, requirements analysis
  • The software resulting from each iteration/sprint is not a prototype or proof of concept, but a subset of the final system
• More broadly, viewing an iteration as a self-contained mini project, activities in many disciplines (requirements analysis, testing, etc.) occur within a single iteration
Although IID is in the ascendancy today, it is not a new idea

• 1950s “stage-wise Model” – US Air Defense SAGE Project
• IBM created the IID method of Integration Engineering in the 1970s

IID Programs tend to be less structured in the beginning, and therefore reliable estimates of cost and schedule may not be available until 10-20% of the project is complete

(in a recent program I saw a cost variance during the first 4 increments of 45% per size metric)

• The current emphasis on agile software development processes maps directly into the IID Concept
### Typical IID Problems – SLOC Count

One could suggest that these problems are common to all Software Intensive Programs
What is Agile Software Development?

• In the late 1990s, several methodologies received increasing public attention

• Each had a different combination of old, new, and transmuted old ideas, but they all emphasized:

  • Close collaboration between the programmer and business experts
  • Face-to-face communication (as more efficient than written documentation)
  • Frequent delivery of new deployable business value
  • Tight, self-organizing teams
  • And ways to craft the code and the team such that the inevitable requirements churn was not a crisis
“We are uncovering better ways of developing software by doing it and helping others do it

Through this work, we have come to value:

- Individuals and interactions over processes and tools
- Working software over comprehensive documentation
- Customer collaboration over contract negotiation
- Responding to change over following a plan

That is, while there is value in the items on the right, we value the items on the left more”
Principles behind the Manifesto

- **Principles of Agile Developers:**
  - Our highest priority is to satisfy the customer through early and continuous delivery of valuable software
  - Welcome changing requirements, even late in development
    - Agile processes harness change for the customer’s competitive advantage
  - Deliver working software frequently, from a couple of weeks to a couple of months, with a preference to the shorter timescale
  - Business people and developers must work together daily throughout the project
  - Build projects around motivated individuals
    - Give them the environment and support they need, and trust them to get the job done
  - Working software is the primary measure of progress
Principles behind the Manifesto

• Principles of Agile Developers (continued):
  • The most efficient and effective method of conveying information to and within a development team is face-to-face conversation
  • Agile processes promote sustainable development
    • The sponsors, developers, and users should be able to maintain a constant pace indefinitely
  • Continuous attention to technical excellence and good design enhances agility
  • Simplicity, the art of maximizing the amount of work not done, is essential
  • The best architectures, requirements, and designs emerge from self-organizing teams
  • At regular intervals, the team reflects on how to become more effective, then tunes and adjusts its behavior accordingly

- **Recent observations regarding the utilization of Agile development approaches within the Federal Government:**
  - May work best when the project is more requirements-driven than schedule-driven
  - Beginning to see common usage in Department of Defense (DoD) unclassified (e.g. Marine Corps) and classified programs (e.g. Naval Reconnaissance Office [NRO])
Differences of Agile and Non-Agile

Recent observations regarding the utilization of Agile development approaches within the Federal Government (continued):

- Being talked about within emerging National Aeronautics and Space Administration (NASA) projects
- Being used in DHS
- It sounds very much like what we called “rapid prototyping”
- More common than is being recognized
Welcome to Agile

• What is an agile development approach?
• Depends on the flavor:
  • Agile Modeling
  • Lean Development (LD)
  • Adaptive Software Development (ASD)
  • Exia Process (ExP)
  • Scrum
  • eXtreme Programming (XP)
  • Crystal methods
  • Evolutionary – EVO
  • Feature Driven Development (FDD)
  • Dynamic Systems Development Method (DSDM)
  • Various Unified Processes (UP): agile, essential, open
  • Velocity tracking, and more!
What do they have in common?

• Agile projects are focused on key business values
  • What does the client really, really, really want?
  • Deliver what the client wants at the end of the project, not what the client wanted at the beginning of the project

• They all contain a project initiation stage (aka planning)
  • Project scope, constraints, objectives, risks are all officially documented

• Short (very short) development of chunks of features/stores/requirements/needs/desires (aka sprints)

• Constant feedback
  • The one place where we can actually find short meetings

• Customer participation is MANDATORY or no-go!

• Refactoring; as in, do it again and this time get it right, or better

  Project Size set to 250 Function Points. Calculated Using SEER for Software
Other Current Research

Empirical evidence indicates development costs may be reduced by 10 to 20 percent for Iterative Driven Programs. In a “The Raytheon Agile Journey” a presentation by Cindy Molin (Director, SW Engineering) and Katherine (K) Sementilli (Deputy, SW Engineering), Raytheon Missile Systems on June 22, 2012 the following efficiencies based on agile development are observed (based on over 250 projects and over 5 million ELOCs):

Agile Development Results

• 20% of Raytheon SW Engineering Development Productivity
• 25% productivity increase Agile vs Non-Agile
• 10% variability reduction Agile vs Non-Agile
• 50% faster for Agile vs Non-Agile
• Time on task for an average work day 30% more for Agile vs Non-Agile
Scrum Size:
- 1-10 people (have seen up to 20)

Sprint Length:
- 1-6 weeks (have seen up to 13 weeks) (13 conveniently give 4 sprints per year)

Story Points* per Sprint:
- 6-9 Story Points per Sprint

There seems to be a real avoidance of using Function Points or SLOC in many of these efforts.

(But trust me a size metric exists somewhere within the development community)
Four Estimating Processes

• **Process 1: Simple Build-up approach** based on averages can be defined as:
  • Sprint Team Size (SS) \( \times \) Sprint length (Sp time) \( \times \) Number of Sprints (# Sprints)

• **Process 2: Structured approach** based on established “velocity” – most often used internally by the developer since detailed/sensitive data are available to them

• **Process 3: Automated Models approach** based on a size metric – which may be difficult to quantify

• **Process 4: Factor/Complexity approach** based on data generated in early iterations
A Word About 2014 Rates

• Developers and Tester - $70 to $200 per hour, median team rate about $125
• Agile Coach - $100 to $200 per hour, average about $150
• Business Analyst - $125
• Average Team Rate of about $115

WARNING: THESE ARE BROAD AVERAGE I HAVE FOUND THIS YEAR
Process 1: Build-Up Approach

When a program is comprised completely of agile sprints, we can use industry norms or program plans to develop an estimate

- Process 1 is defined as:
  - SS $\times$ Sp time $\times$ # Sprints
  - SS (normally 1-10 people) $\times$ Sp time (normally 0.25 to 1.25 months) $\times$ # Sprints
  - Frequently used by independent estimators since actual data are often unavailable
  - Remember to factor in time for demonstrations/user feedback
  - Can develop a point estimate and a range
  - Works well for small programs

The weakness of this approach is justifying the team size, number of sprints, sprint length and total required to meet the requirement.
Process 2: Structured Approach based on “Velocity”

- Process 2 can be summarized by:
  1. Express requirements in the same size metric used by the developer; normally Features, Feature Points, Use Case Points, Story Points, ... What the size metric is unimportant as long as it is consistently used across this program*
  2. (optional). Use a process to rank the size metric: small, medium, large using something like Fibonacci sequence, planning poker
  3. Estimate and/or document the velocity (number of size metrics per time period) at which the Agile team has worked
  4. Estimate and/or document the historic cost per size metric for the Agile team
  5. Spread the sprints over time to develop time-phased estimate

* I would hope that over time we could develop standards for agile development across the various size metrics and programs. However, since these metric often do not conform to a “standard” this is an elusive task. But an average over several early interactions may be very accurate for a specific [program.
What is a Use Case Point?

- A weighted count of actors and use cases
  - Actor weight is classified as:
    - 1 – Simple: highly-defined and elemental, such as a simple API call
    - 2 – Average: protocol-driven interaction, allowing some freedom
    - 3 – Complex: potentially complex interaction
  - Use Case weight is classified as:
    - 5 – simple: 3 or fewer transactions
    - 10 – average: 4-7 transactions
    - 15 – Complex: more than 7 transactions
Moving to Automated Models

- Step 5 of the previous slide suggested you time-phase the Sprints
  - When you do this, the results often resemble the Rayleigh Function used in modern software models

- This observation leads to the third estimating process
Process 3: Automated Model Approach

• The “Parameter” settings within automated models can be adjusted to estimate costs and schedule for complex/large projects
  • The “environmental factors” in SEER, PRICE, SLM, and COCOMO II have been adjusted to reflect Agile practices and therefore Iterative Development
  • Remember, the size metric is still the key cost driver, which is even less certain in agile programs than traditional ones
Process 4: Factor/Complexity Approach

• In a normal IID program, the initial program estimate must be based on broad parameters with wide ranges – analogy to previous programs and/or generic models

• Specific iterations/sprints can be estimated using the agile estimating processes previously presented

• The real question is: how do we estimate the cost of future Increments (time boxes)?

• The following slides present Process 4 Factor/Complexity Approach
Process 4: Factor/Complexity Approach

• Step 1: Select a **Baseline Increment** (often the last successful increment) for the program

• Step 2: Carefully analyze this baseline increment – this analysis could be based on SLOC, function points, features, requirements, dollars, or some other metric

• Step 3: For each new increment, compare the expected functionality and complexity of the new increment to the baseline (or last successful) increment

• Notional functional and complexity factors are presented on the next slide
Process 4: Factor/Complexity Approach

• These initial set of factors came from the environmental factor from traditional software cost models
• Step 4: Because each Increment is a mini project, use a Rayleigh or simple Beta Curve (such as a 60/50 Beta curve) to phase costs
• However, do not be surprised if you encounter programs that are truly operated and manages as Level of Effort (LOE)
Process 4: Factor/Complexity Approach

- Step 5: The project can define the length of each increment – likely between 4 and 14 months

![Incremental Beta Chart]
Issues for Project Management

• Cost and Schedule modelers usually want well-defined program requirements and size metrics early in the lifecycle – the nature of IID programs argues against this
  • IID programs tend to be less structured in the beginning, and therefore reliable estimates of cost and schedule may not be available until 10-20% of the project is complete

• Initial contracts tend to be Fixed Price or LOE
  • This does not imply poor value to the project
  • It does imply that key “value-added” metrics may not be identified or collected

• “Time Boxing” tends to resolve the individual scheduling issues, but not the total program length issue
  • A specific cost estimating strategy is required to accurately plan for resources
Issues for Project Management

• If a program has too many planned Increments (10 or more), it may not be a well-defined program and could spin out of control or just become an LOE research project

• Establishing and monitoring metrics becomes critical

• “To be able to adopt an empirical approach to project management and control, we must be able to objectively demonstrate and measure how much progress the project has made in each iteration
  • Possible ways to measure progress include:
    • Number of products and documents produced
    • Number of lines of code produced
    • Number of activities completed
    • Amount of budget/schedule consumed
    • Number of requirements verified to have been verified implemented correctly”
Schedule Analysis

• Due to the short length of increments (generally 9-12 months) and continuity between increments, phasing the costs within a specific increment is less important.

• However, the “million dollar questions” for incremental and agile programs (where requirements definition and documentation are less detailed, and the development is more flexible/emergent) are:
  • What will the program look like at Initial Operational Capability (IOC)?
  • How many increments will it take?
  • How long is each increment going to last?

• Cost estimators are going to have to adjust, and examine these programs as a schedule analyst might to produce credible lifecycle estimates.
Summary

• Fixed Price and/or LOE contracts in the early phases should be written so that key “value-added” metrics are collected and reported during each increment.

• Estimators may have to employ a variety of software estimating methodologies within a single estimate to model the blended development approaches being utilized in today’s development environments:
  - An agile estimating process can be applied to each iteration/sprint.
  - Future Increments can be estimated based on most recent/successful IID performance.

• Cost estimators will have to scrutinize these programs like a schedule analyst might to determine the most likely IOC capabilities and associated date:
  - The number of increments are an important cost driver as well as an influential factor in uncertainty/risk modeling.
Summary

• All of the estimation methods are susceptible to error, and require accurate historical data to be useful within the context of the organization.

• When developers and estimators use the same “proxy” for effort, there is more confidence in the estimate.
