

# Rodent Habitat

## Studying Animals in Space

### Aboard the International Space Station

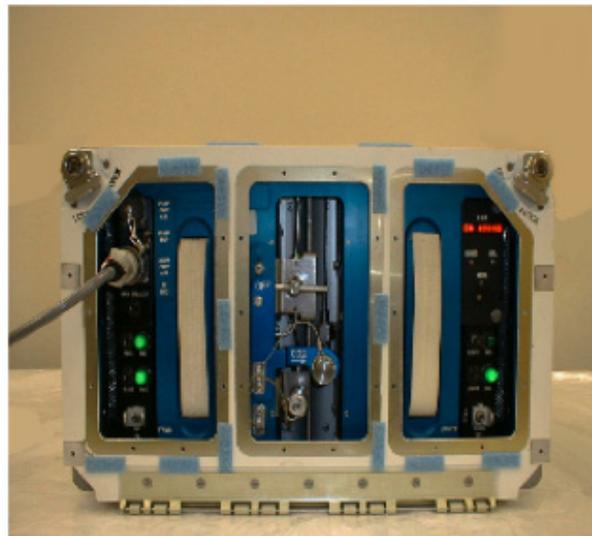

The Rodent Habitat provides a research platform aboard the International Space Station for long-duration rodent experiments in space. Such experiments will examine how microgravity affects the animals, providing information relevant to human spaceflight, discoveries in basic biology, and knowledge that can help treat human disease on Earth.

Rodent spaceflight experiments have contributed significantly to our understanding of the effects of microgravity on biological processes that are directly relevant to humans in space. Rodent studies provide information at the whole biological system level about the effects of microgravity on the structure and function of the sensori-motor, musculoskeletal, nervous, cardiovascular, reproductive and immune systems. Specific research questions are defined in the National Research Council's 2011 Decadal Survey Report, "Recapturing a Future for Space Exploration: Life and Physical Sciences Research for a New Era."

Historically, short-term rodent experiments have been transported into Earth's orbit aboard various vehicles, including Russian biosatellites and NASA's space shuttle. The International Space Station is the first essentially "permanent" orbiting science laboratory that offers the opportunity for longer-term experiments in space. In 2011, NASA's Ames Research Center was authorized to develop the Rodent Habitat to enable rodent research aboard the space station.

This hardware development project leverages the experience gained from 27 prior flight experiments with rodents using a space

shuttle-based system. Advanced capabilities of the new Rodent Habitat include providing housing for longer duration studies than the previous system allowed. In the post-shuttle era, the hardware must also support safe transport of rodents on the commercial re-supply service vehicle SpaceX Dragon.

Rodent Transporter to the space station

The new system has three major components. The first is the Transporter that will safely transport rodents to the space station. The second is the Animal Access Unit that will be used to transfer the rodents upon arrival at the station from the Transporter into the Rodent Habitat. The Rodent Habitat unit will provide long-term housing for rodents aboard the station.

The maiden voyage of the Rodent Habitat, Rodent Research-1, will launch on SpaceX-4 in 2014. The goal of the first flight is to

validate hardware performance and for the station crew to demonstrate critical research operations on-orbit. Twenty mice will be aboard the space station for a period of up to 30 days.

Animal Access Unit – transfer aboard the space station

NASA and the Center for the Advancement of Science in Space (CASIS) are developing space flight experiments that will use the Rodent Habitat. The first science mission, Rodent Research-2, will be flown on SpaceX-6 in late 2014. Ultimately, NASA will be conducting animal studies that will last 3 to 6 months.

Under the direction of the International Space Station Utilization Office and the Space Biology

National Aeronautics and Space Administration

Project, The Rodent Habitat is being developed at NASA's Ames Research Center, benefiting from the expertise within the Space Biosciences Division. Lockheed Martin is performing hardware development and providing science and mission operations support. BioServe Space Technologies, Boulder, Colo., is developing environmental control and life support systems required during launch operations.

This project is supported by the International Space Station Program at NASA's Johnson Space Center and the Space Biology Project at NASA's Ames Research Center. Funding for Space Biology comes from the Space Life and Physical Sciences Research and Applications Division within the Human Exploration and Operations Mission Directorate at NASA Headquarters.
