DATE: December 15, 2023

SUBJECT: Toxicological Assessment of ISS Air and Water Quality: March 28, 2022 – September 29, 2022 (Increment 67) Including Boeing OFT-2 and SpX-25 Ingresses

SUMMARY: Based on these data, air quality was acceptable on ISS for this period, and potable water remains acceptable for crew consumption.

**AIR QUALITY**

Nine archive air samples were collected in mini grab sample containers (mGSCs) on ISS during Increment 67. These consisted of 7 routine samples and 2 ingress samples. A summary of the key air quality indicators from the Increment 67 mGSC samples is provided in Table 1A. Additionally, three sets of formaldehyde badges were deployed in the US Lab and the Russian Service Module (SM) during Increment 67. Table 1B includes a summary of the formaldehyde levels measured on these badges.

Data tables containing measured concentrations and corresponding T-values based on appropriate Spacecraft Maximum Allowable Concentrations (SMACs) for compounds present at levels above the laboratory reporting limit are attached to this report. Complete data tables, which include compounds assessed but not detected, are available upon request. Pressure readings for the mGSCs indicate that all Increment 67 samples were acceptable. The mean relative recoveries of the three surrogate standards were all within acceptable limits for all samples.

On-orbit, the Air Quality Monitors (AQMs) automatically collect and analyze samples every 73 hours, which results in 2-3 sampling sessions per unit per week. Monthly average concentrations as well as the Increment average concentrations for compounds measured on the AQMs are presented in Table 2.

**Toxicological Evaluation of ISS Air Quality**

Routine air quality monitoring is performed in-flight using the AQMs. Archive air samples (mGSCs and formaldehyde badges) are collected during each Increment and returned for analysis in the Environmental Chemistry Laboratory. Data from the ground analyses complement the in-flight data and provide a more complete understanding of air quality on the ISS. Despite results which required additional scrutiny, the routine mGSC samples that returned on Boeing OFT-2, SpX-25, and SpX-26 confirmed that air quality was acceptable during this Increment. **T-values calculated using data from four of the routine archive samples met the 180-d T-value guideline ( $T < 1$ ), indicating no concern for crew health. T-values from 3 archive samples slightly exceeded 1 but are not regarded as a concern for human health (see below).**

**Table 1A. Analytical summary of ISS air analyses from mGSCs during Increment 67**

Return Flight	Sample Location	Sample Date	Freon 218 (mg/m <sup>3</sup> )	Alcohols <sup>a</sup> (mg/m <sup>3</sup> )	T-Value <sup>b</sup> (units)
Boeing OFT-2	US Lab	4/13/2022	5.9	8.9	0.8
SpaceX-25	JPM	4/13/2022	6.2	7.6	0.6
Boeing OFT-2	Boeing OFT-2 ingress	5/21/2022	<1.5	1.4	0.1 (0.0)
SpaceX-25	US Lab	6/22/2022	<1.5	6.7	0.4

SpaceX-25	US Lab	8/1/2022	40
SpaceX-25	SM	8/1/2022	18
<i>Guideline</i>			<120

The reported concentrations for several individual compounds detected during Increment 67 are elevated compared to previous Increments. The average, rounded T-value calculated from the nominal Increment 67 mGSC samples was 1.2 (Figure 1), which is markedly higher than the T-value from Increment 66 (0.5), but similar to the Increment 65 value (0.9). The T-value in Increment 67 is primarily driven by the presence of acrylonitrile, which has been intermittently present on ISS since early 2021. The T-value generated by AQM data was markedly lower, as acrylonitrile is not measured by AQMs (Figure 2). Three mGSC samples taken during Increment 67 contained acrylonitrile at concentrations above the 180-day interim SMAC (0.07 mg/m<sup>3</sup>): August 1, 2022, in the US Lab and Columbus, and in the Russian SM on September 14, 2022. Acrylonitrile levels in the September sample from the Russian SM were 0.19 mg/m<sup>3</sup>, which contributed 93% of the T-value on that date (Figure 3).

TRACE: &gt;MDL, &lt;MQL (Minimum Quantification Limit)

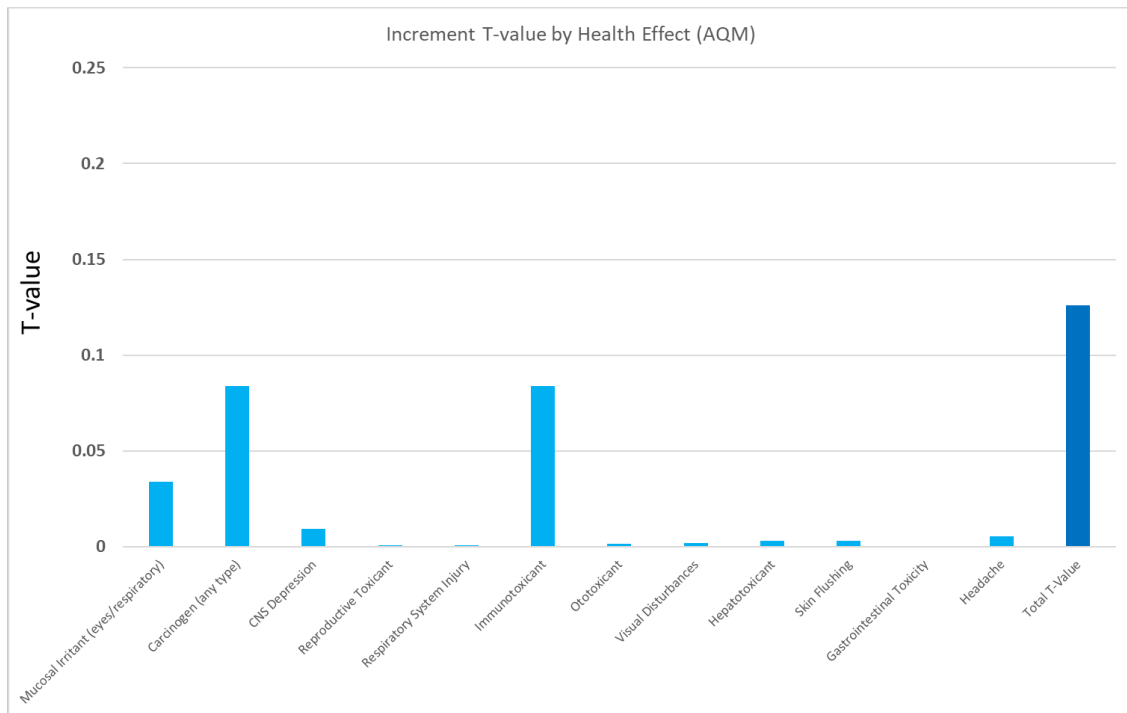

ND: Not detected; &lt;MDL (Minimum Detection Limit)

The source of acrylonitrile has not yet been identified. Several potential sources have been investigated, including technological demonstration hardware for the removal of CO<sub>2</sub> and a 3-D printing payload. However, no activities or anomalies with any potential source have been correlated with the observed increase in acrylonitrile concentration.

Despite the presence of acrylonitrile in the ISS atmosphere at levels above the 180-day SMAC, crew have not reported symptoms (i.e., irritation, dizziness, headache). As indicated in Figure 3, data from subsequent sampling in Increment 68 indicated that acrylonitrile was not present in any samples from October or December 2022. Levels did not approach the 7-d interim SMAC level of 0.4 mg/m<sup>3</sup>, and the duration of acrylonitrile in ISS air above the 180-d SMAC was at most on the order of 45-55 days (August 1 to September 14, 2022).

**Figure 1. GSC-Derived T-values for Increments 58-67**

**Figure 2. AQM-Derived T-Values by Health Effect for Increment 67**

Alcohol values for all seven of the routine mGSC samples returned on SpX-25 exceeded the ECLS guideline of <math>5 \text{ mg/m}^3</math>. The levels are mostly attributable to ethanol, which remained near or above  $5 \text{ mg/m}^3$  throughout the Increment. Measured levels do not present a risk to crew health but are a potential concern for the water recovery system.

Levels of octafluoropropane (Freon 218) continue to be very low in ISS air compared with historical measurements.

**Figure 3: Acrylonitrile concentrations in ISS air from January 2021 through December 2022.**  
ND: not detected

All seven routine mGSC samples collected during Increment 67 contained a  $\text{CO}_2$  concentration below the limit documented in Flight Note F091532D, which requests that the 24-hour average concentration not exceed a 24-hour average of  $3.0 \text{ mmHg}$  ( $7100 \text{ mg/m}^3$ ,  $4000 \text{ ppm}$ ) on the US segment. While mGSC  $\text{CO}_2$  sampling provides a snapshot of the  $\text{CO}_2$  concentration, real-time  $\text{CO}_2$  data are available from a sensor in the Columbus module, and intermittently from the Major Constituent Analyzer (MCA) (Figure 4). To preserve the longevity of the instrumentation, MCAs are only activated during EVA activities, crew metabolic characterization, tech demo analysis, anomaly resolution, and when requested by crew surgeons. Overall,  $\text{CO}_2$  concentrations (per data from the Columbus sensor and Lab MCA) were well-controlled throughout the Increment. Excursions above  $5 \text{ mmHg}$  were noted in mid-May 2022 in conjunction with EVA activities. Peaks were also observed in May and September but are associated with MCA startup; data from Columbus indicated markedly lower concentrations. The arrival of Axiom-1 (Ax-1), a private astronaut mission to ISS, resulted in an ISS crew complement of 11. Ax-1 departed on May 5, after which  $\text{CO}_2$  concentrations stabilized below  $2 \text{ mmHg}$ .

**Figure 4. Environmental CO<sub>2</sub> Concentrations on ISS During Increment 67 (mmHg)**

Three sets of passive formaldehyde badges were deployed on ISS during Increment 67. Results from analysis of these badges indicated that formaldehyde remains at or below the historical range observed on ISS, and concentrations are well below the SMAC of 120  $\mu\text{g}/\text{m}^3$  (Figure 5). For most of the Increment, formaldehyde was not detected in either the US Lab or the Russian SM but rose in the US Lab in the August sample.

**Figure 5: Formaldehyde Concentrations from February 2016 to February 2022**

*Boeing OFT-2 Ingress*

An ingress sample was collected in Boeing's uncrewed Starliner Orbital Flight Test 2 (OFT-2) vehicle on May 21, 2022. The collection time for this sample was not recorded, so it is unclear how long after hatch opening it was collected. This sample contained 3300 mg/m<sup>3</sup> CO<sub>2</sub> (1.4 mmHg, 1800 ppm), which is slightly lower than typical ISS atmosphere and could suggest equilibration with the ISS atmosphere prior to collection. However, ethanol levels in the vehicle (0.57 mg/m<sup>3</sup>) were significantly lower than ISS levels during this period (5.6-6.0 mg/m<sup>3</sup>). This makes interpretation of these results difficult as there should not have been any sources of CO<sub>2</sub> inside the vehicle. **Regardless, the T-value for OFT-2 ingress was 0.02, which is well below levels of concern for human health.**

*SpX-25 Ingress*

An ingress sample was collected in SpX-25 on July 16, 2022, at 16:44 GMT. Unfortunately, the time at which the hatch was opened was not recorded. The sample contained 6400 mg/m<sup>3</sup> CO<sub>2</sub> (2.7 mmHg, 3600 ppm), markedly higher than the level on ISS during this period. These elevated levels may be a result of the presence of laboratory animals (Rodent Research-22) in the vehicle. Levels of ethanol and methanol were markedly lower inside the SpX-25 vehicle compared to the ISS level over the same period, indicating a low level of mixing. **The T-value for SpX-25 ingress was 0.1, well below levels of concern for human health.**

**WATER QUALITY**

In total, seven water samples were collected from the US Segment during Increment 67 and returned on Crew-3, Crew-4 and SpaceX-25. Four of these were potable water samples collected from the US Potable Water Dispenser (PWD): two hot water and two ambient water samples. The remaining samples were non-potable water, including a WPA product water sample collected from the PWD Aux Port and two samples each of US condensate and wastewater. Summaries of select analytical results from the Increment 67 samples are provided in Tables 3A and 3B.

Return Mission	Sample Location	Sample Date	TOC (mg/L)	DMSD (mg/L)	Methyl Sulfone (mg/L)	Conductivity (µS/cm)	Total Iodine (mg/L)
Crew-3	PWD Ambient	3/29/2022	0.78	1.6	0.24	1	0.06
Crew-3	PWD Hot	4/19/2022	0.89	1.9	0.21	1	<0.05
Crew-4	PWD Ambient	8/15/2022	0.42	<1	0.12	1	<0.05
Crew-4	PWD Hot	9/14/2022	0.15	<1	0.14	1	<0.05

### Toxicological Evaluation of ISS Water Quality

Routine water quality monitoring is performed in-flight using the total organic carbon analyzer (TOCA). Results from these analyses provide a general indication of overall water quality. Typically, archive water samples are also collected during each Increment and returned for comprehensive analysis in ground laboratories. Data from the ground analyses complement the in-flight data and provide a more complete understanding of water quality on the ISS.

#### *Potable Water*

**Concentrations of all chemicals detected in the potable water samples met the requirements listed in SSP 41000, System Specification for the International Space Station and JSC 63414, Spacecraft Water Exposure Guidelines (SWEGs).** Total organic carbon (TOC) concentrations from in-flight (PWD TOC and WPA TOC) and ground analyses (Archive TOC) performed between April 2021 and March 2022 are shown in Figure 6. The TOC concentrations in the four potable samples continued to be low and were well below both the specification for the US segment (<3 mg/L) and the 100-day SWEG (5 mg/L).

The DMSD concentrations were above the 1 mg/L reporting limit in the PWD hot and ambient samples (1.6 and 1.9 mg/L) from March, April, August, and September 2022. Methyl sulfone was detected in two of the four potable water samples at levels well below the SWEG of 1,500 mg/L. Silicon was detected in three of four samples (0.5-0.6 mg/L). Based on these results, the water produced by the Water Processor Assembly (WPA) met all US potability requirements.

Iodine is a biocide used on the US Segment. It is added to the water produced by the WPA but removed prior to crew consumption to avoid potential thyroid dysfunction. The total iodine level in one of four potable samples collected from the PWD was slightly above the reporting limit (0.05 mg/L) but below the potability limit, indicating effective removal of iodine in water intended for consumption. For additional information regarding microbial analyses, see the Increment 67 post-flight report generated by the JSC Environmental Microbiology Laboratory.

**Figure 6. Total Organic Carbon (TOC) trending in US Potable Water from Archive Water Samples and On-Orbit TOCA (PFU3)**

### *Condensate*

The condensate sample collected on April 13 and August 5, 2022, contained TOC levels of 131 and 163 mg/L, respectively. Both of these concentrations are near the historical average of 150 mg/L. Organic compounds detected at or above 1 mg/L are listed in Table 4. Ethanol was markedly above historical average concentrations, consistent with the higher-than-historical levels of ethanol in ISS air. Silicon was present at 6.2-10.3 mg/L and can mostly be accounted for by the presence of DMSD. Zinc and nickel were detected above 0.1 mg/L. Ammonium was present at 31-39 mg/L, near the historical average of 37 mg/L. All of these compounds were effectively removed by the WRS, as evidenced by the low or undetectable levels of these species in the potable samples.

**Table 4: Organic Compounds Detected >1 mg/L in US Condensate**

Compound	Condensate (mg/L)		Historical average (mg/L)
	April 13, 2022	August 5, 2022	
Benzoic acid	1.7	1.9	1.1
Benzyl alcohol	5.8	4.7	12.9
2-propanol (isopropanol)	3.1	2.3	1.4
Acetone	4.4	5.0	1.9
Ethanol	114.0	70.5	47.3
Methanol	9.1	6.7	4.7
1,2-ethanediol (ethylene glycol)	2.2	4.5	5.7
1,2-propanediol (propylene glycol)	15.1	23.6	27.6
Dimethylsilanediol (DMSD)	16.0	32.0	36.6
Acetate	34.8	76.7	39.7
Formate	2.6	3.5	7.7
Lactate	ND	11.9	5.7
Propionate	ND	1.7	1.0
Caprolactam	ND	1.2	4.6

ND: not detected

*Wastewater*

The wastewater samples from April 13 and August 5, 2022, contained TOC levels of 13 and 86 mg/L (historical average of 41 mg/L). Levels of several organic analytes present in these wastewater samples are shown in Table 5. Silicon was present in the sample at 3-6 mg/L, which can be mostly accounted for by the presence of DMSD. Zinc and nickel were the only metal detected above 0.1 mg/L. Traces of other metals were present in the samples, including aluminum, boron, chromium, copper, manganese, silver, and vanadium. Trace amounts of calcium, magnesium, phosphate, potassium, and sodium were also present. Ammonium ranged from 12.4-22.3 mg/L in the samples, which brackets the historical average (17.5 mg/L). As with the condensate samples, all compounds of toxicological interest were effectively cleaned from the samples by the WRS.

**Table 5: Organic Compounds Detected >1 mg/L in US Wastewater**

Compound	Wastewater (mg/L)		Historical average (mg/L)
	April 13, 2022	August 5, 2022	
Benzyl alcohol	ND	3.4	3.0
2-propanol (isopropanol)	ND	1.6	ND
Acetone	ND	5.7	3.8
Ethanol	ND	54.9	11.4
Methanol	0.62	5.1	4.6
1,2-ethanediol (ethylene glycol)	ND	1.6	1.6
1,2-propanediol (propylene glycol)	ND	10.5	5.2
Dimethylsilanediol (DMSD)	7.7	16.0	15.1
Acetate	ND	21.9	2.4

ND: not detected

Expanded summary tables containing organic carbon recoveries and results for all analytes present at concentrations above reporting limits are included as attachments to this report.
