

# EXPLORESPACE TECH

*TECHNOLOGY DRIVES EXPLORATION*

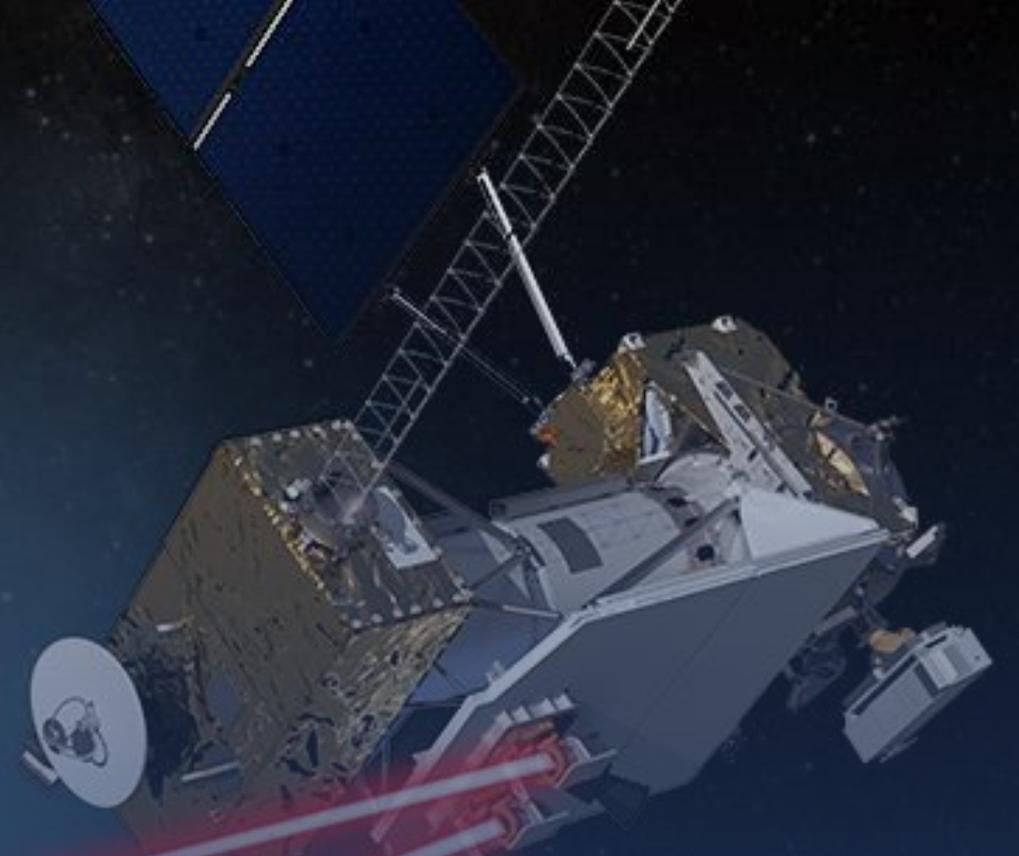

A detailed illustration of the lunar surface. In the foreground, an astronaut in a white spacesuit is kneeling, using a tool on the ground. Another astronaut is visible in the background to the left, working on a piece of equipment. To the right, a lunar lander with a large orange parachute is illuminated by its own lights. The American flag is planted in the ground in the distance. The scene is set against a dark, cratered lunar landscape under a black sky.

# NASA's Endeavor for the Moon

Over 50 years ago, Neil Armstrong and Buzz Aldrin took the first steps on the Moon as part of NASA's Apollo 11 mission.

Now, through the Artemis program, NASA is establishing a renewed presence on the Moon. We will watch this journey through high-resolution videos sent back through laser communications technologies.

LCRD  
LASER COMMUNICATIONS RELAY DEMONSTRATION

# Laser Communications

NASA is developing laser communications to improve our missions and increase data capabilities. Laser communications use infrared light rather than radio waves to transmit data.

Since the beginning of spaceflight, NASA has used radio frequency to send and receive information from satellites in space. In the future, radio and laser communications systems will work together to support missions both near and far.

# The Benefits

Laser communications will provide significant benefits for missions, including:

- 10 to 100 times more data than current radio frequency systems in a single downlink
- Decreased size, weight, and power requirements

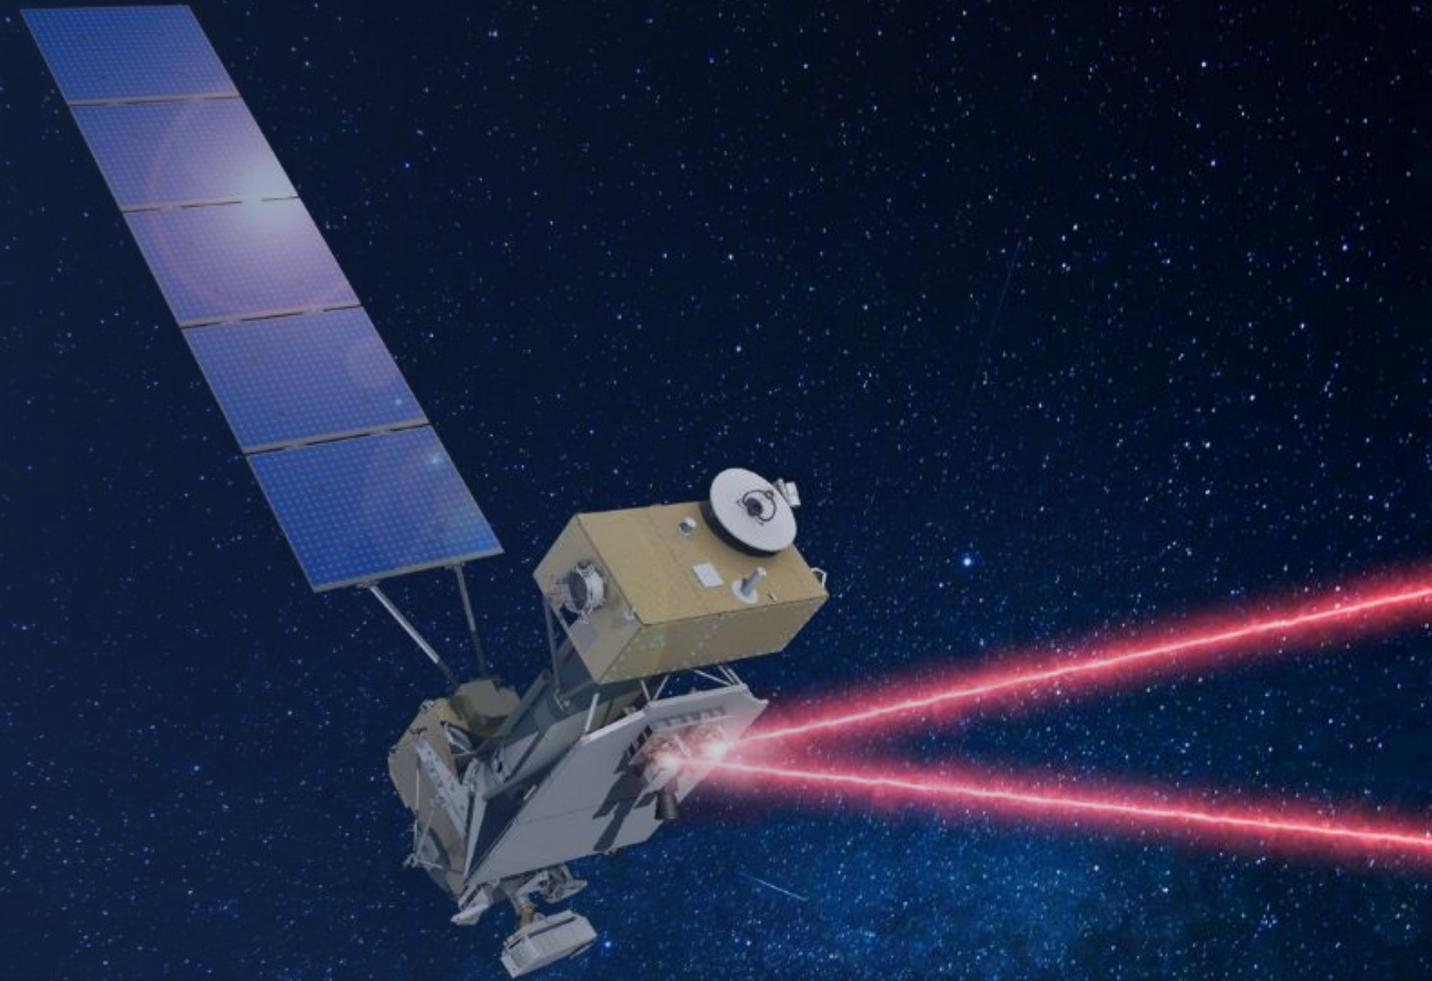

With laser communications supplementing radio, missions will have unprecedented flexibility.

# LCRD

NASA's Laser Communications Relay Demonstration (LCRD) is targeting November 22, 2021, for a launch from the Cape Canaveral Space Force Station.

LCRD will be NASA's first laser communications relay system with two bi-directional optical links.

For its first two years in orbit, LCRD will demonstrate its capabilities with various experiments on the ground and in space.

# How Does LCRD Work?

The background of the slide features a satellite in orbit above Earth. The satellite is positioned in the upper left quadrant, with its solar panels and instruments visible. Below the satellite, the Earth's surface is shown, including the continent of North America and the Atlantic Ocean. The image is overlaid with a semi-transparent blue grid pattern.

LCRD will relay data between two ground stations.

This means it will receive data from one station before sending it on to the next, serving as a communications go-between.

When data is received through one telescope, it will be processed by modems onboard and then sent back out the other telescope to the second ground station.

This mimics the way a future laser communication network might receive data from a spacecraft before forwarding it on to a ground station on Earth.

# Planetary Laser Comm

LCRD is a technology demonstration that will display the value of laser communications relay satellites.

Relay satellites are used around Earth and Mars, but they use radio frequency.

LCRD proves that using laser communications relay systems is possible, regardless if we are near Earth, at the Moon, or even Mars.

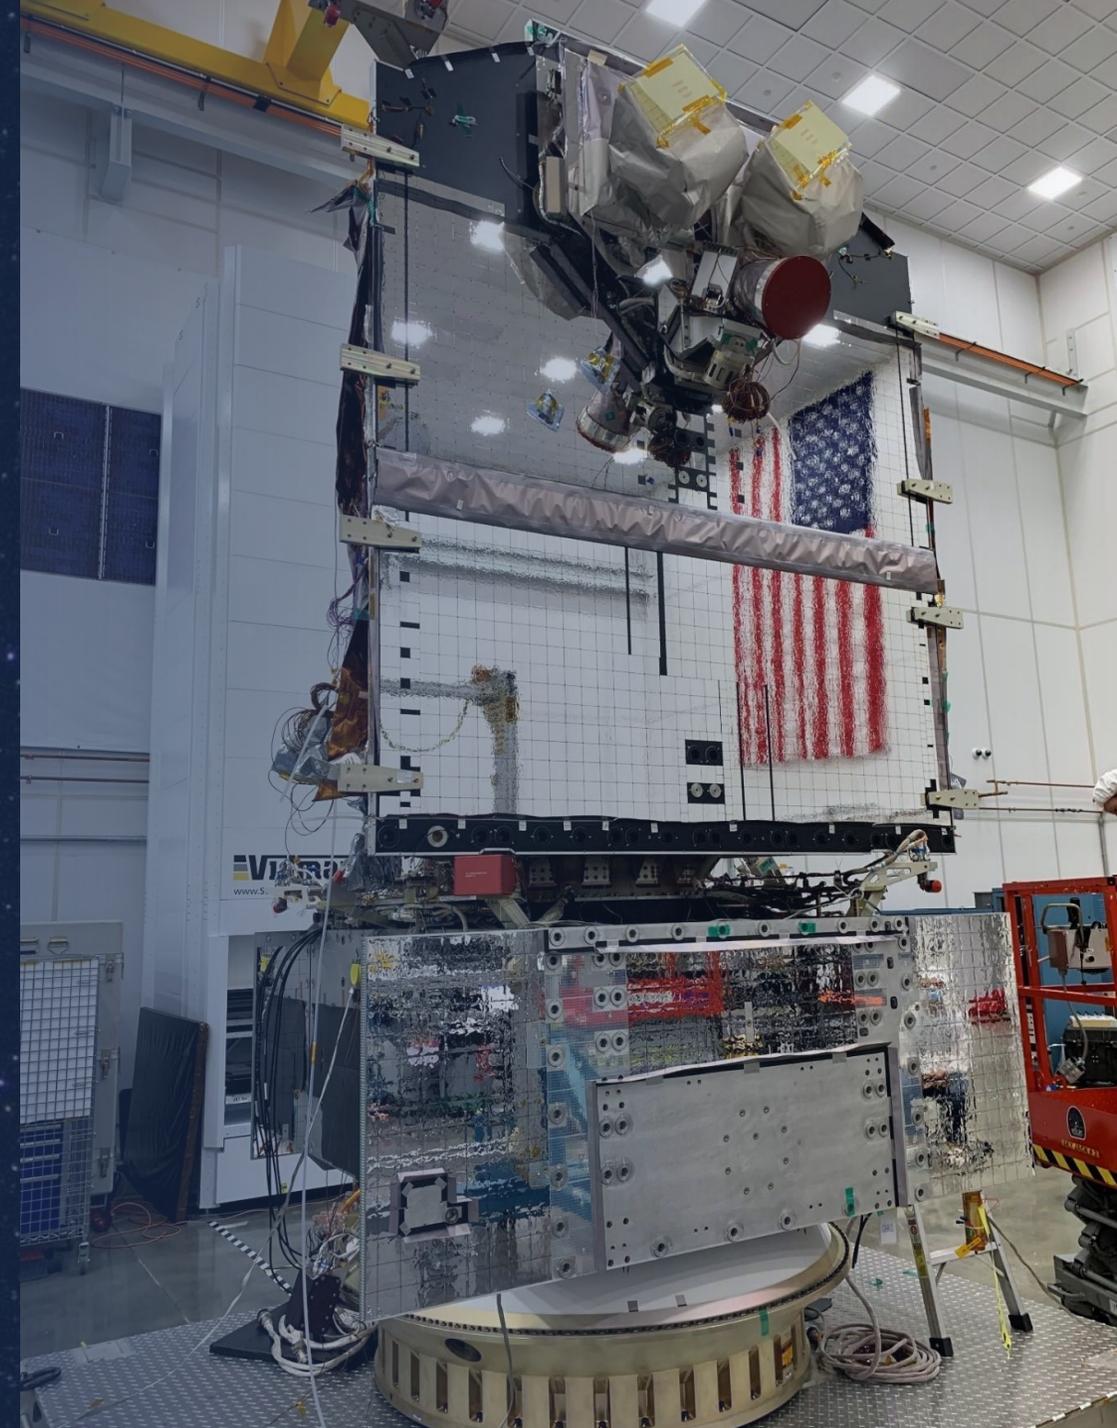

# LCRD

The U.S. Space Force Space Test Program Satellite 6 (STPSat-6) is hosting LCRD, 22,000 miles from Earth in geosynchronous orbit.

The payload will support missions in the near-Earth region, including the International Space Station.

LCRD, like many NASA missions, was created and planned by numerous partners, including:

- NASA's Jet Propulsion Laboratory
- Massachusetts Institute of Technology – Lincoln Laboratory
- U.S. Space Force
- Northrop Grumman
- United Launch Alliance

# LCRD Experimenters

LCRD will spend two years validating its capabilities with a variety of experiments.

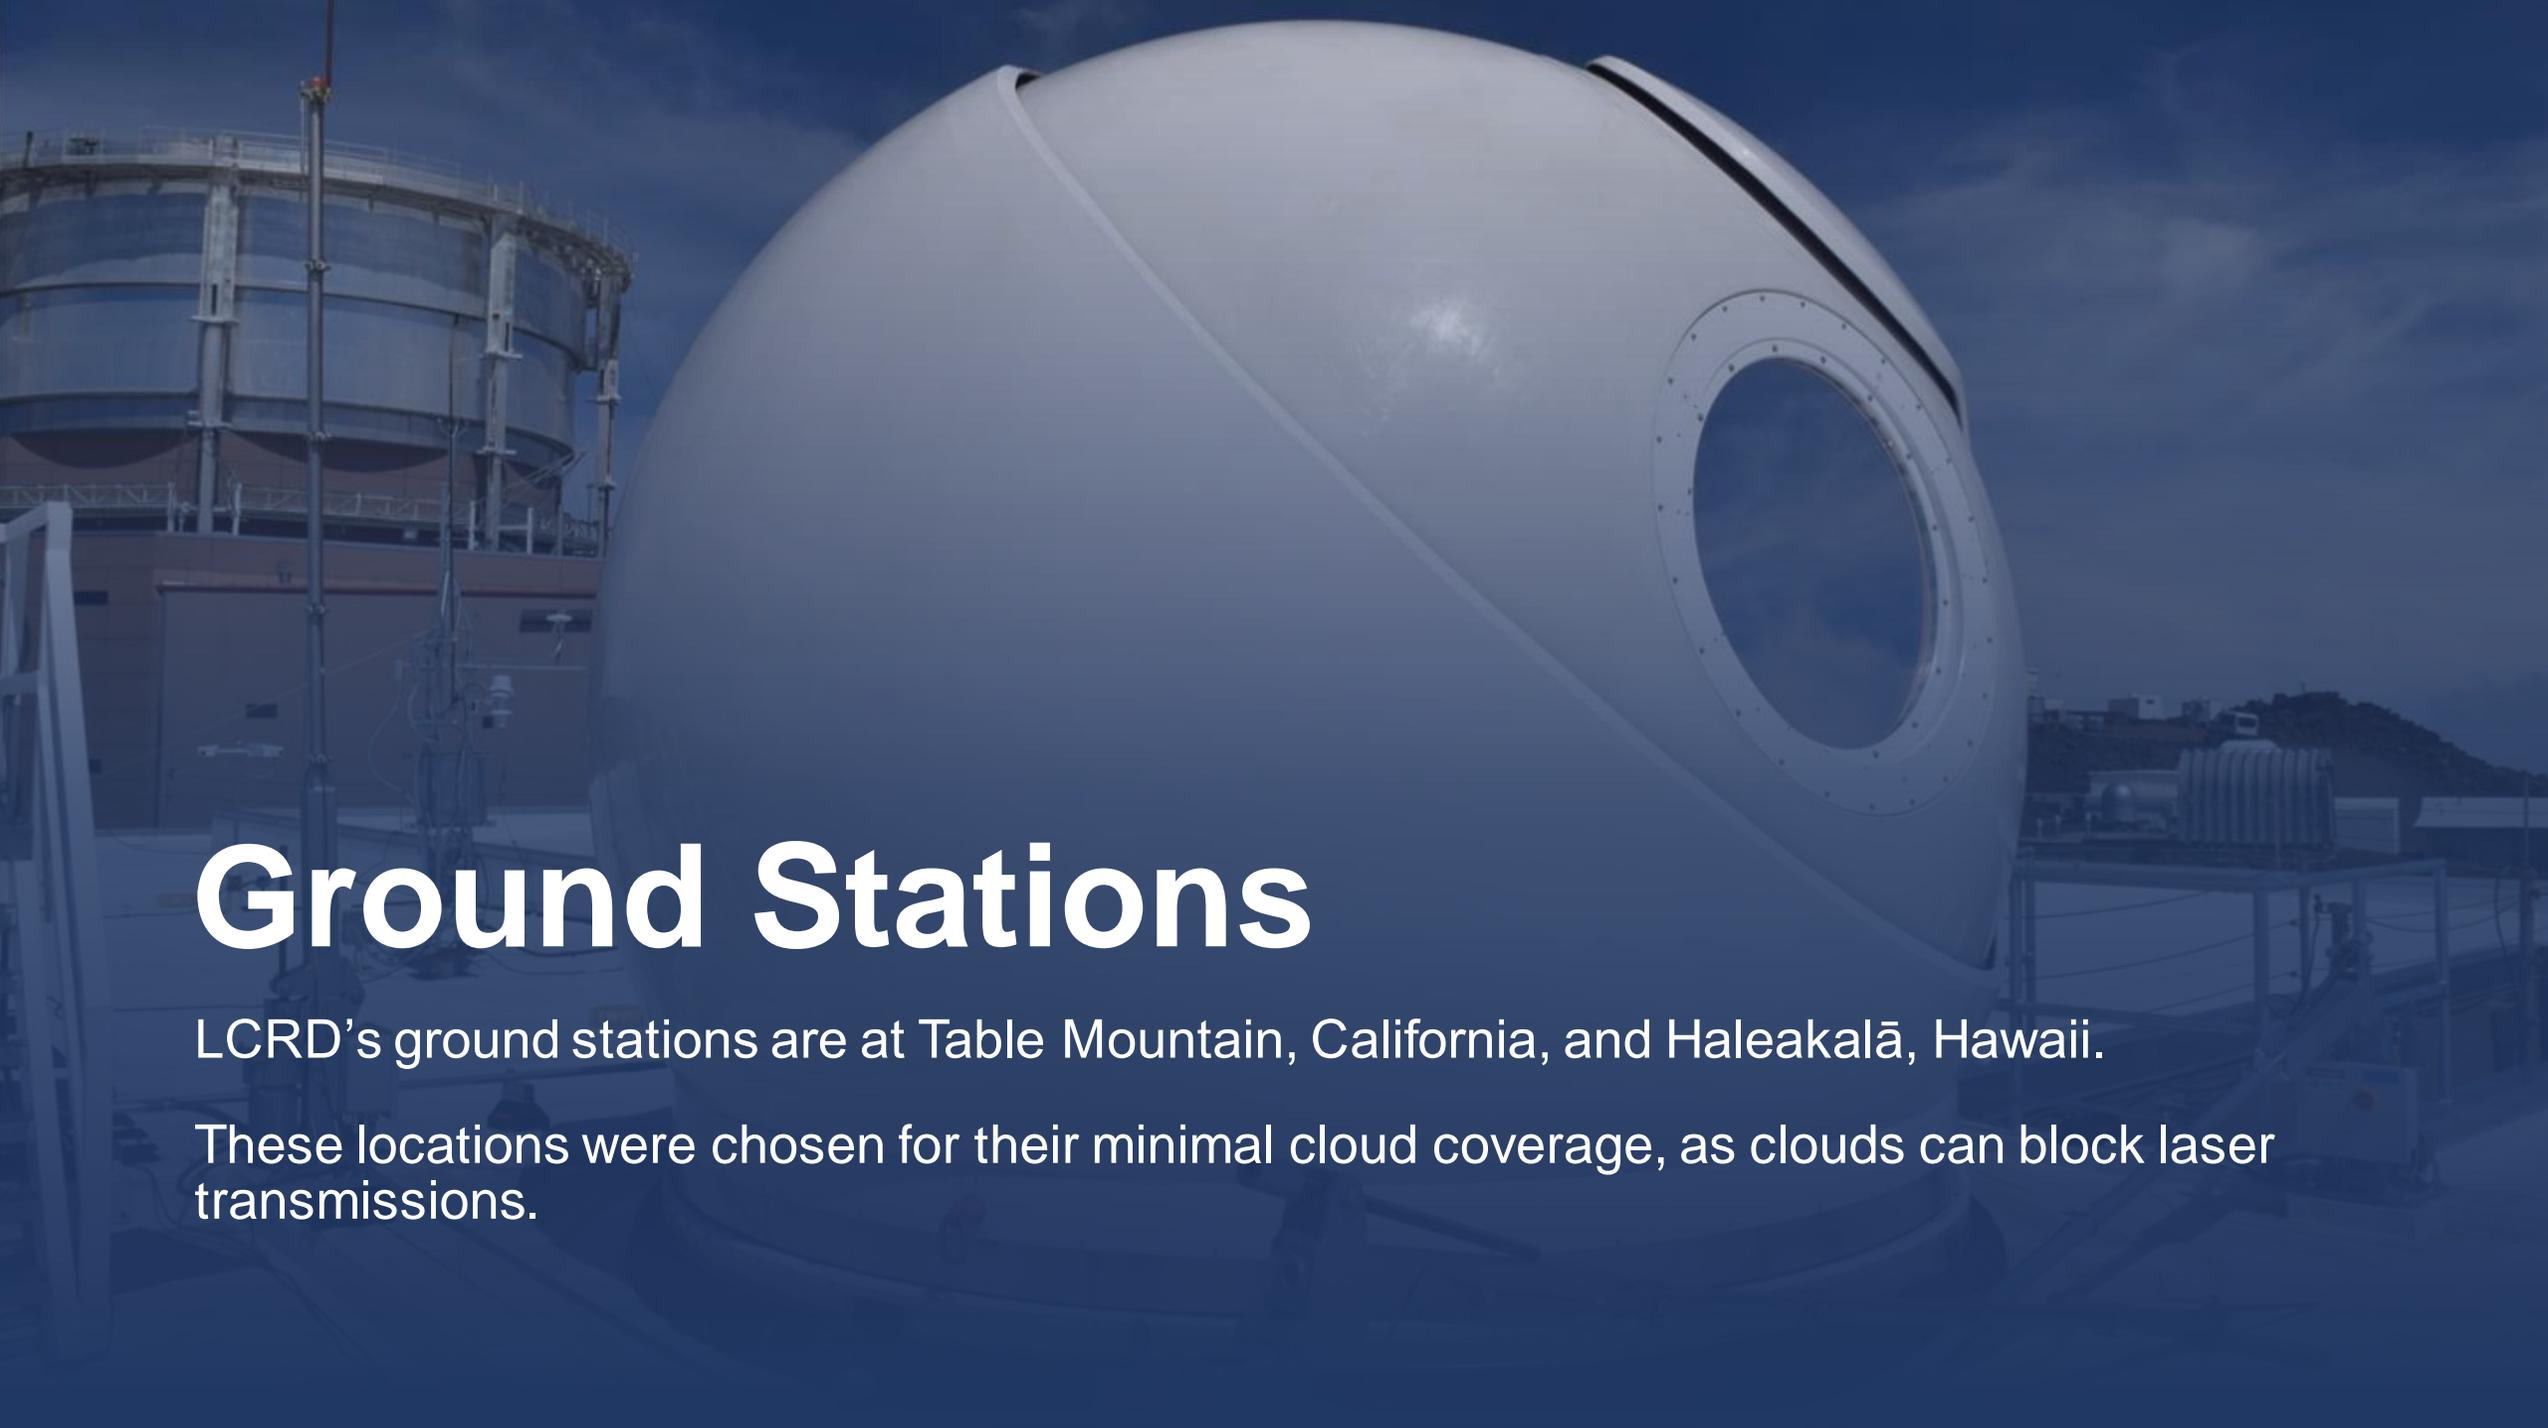

These experiments will increase the aerospace community's knowledge about laser capabilities.

The LCRD Experimenters Program is open to anyone from NASA, other government agencies, industry, academia, and more.

There are opportunities to still be involved. Learn more at <https://go.nasa.gov/3tUZFkq>

# Ground Stations

LCRD's ground stations are at Table Mountain, California, and Haleakalā, Hawaii.

These locations were chosen for their minimal cloud coverage, as clouds can block laser transmissions.

Laser Communications Relay Demonstration

# TBIRD

TeraByte Infrared Delivery

# O2O

Orion Artemis II Optical Communications System

# T-BIRD

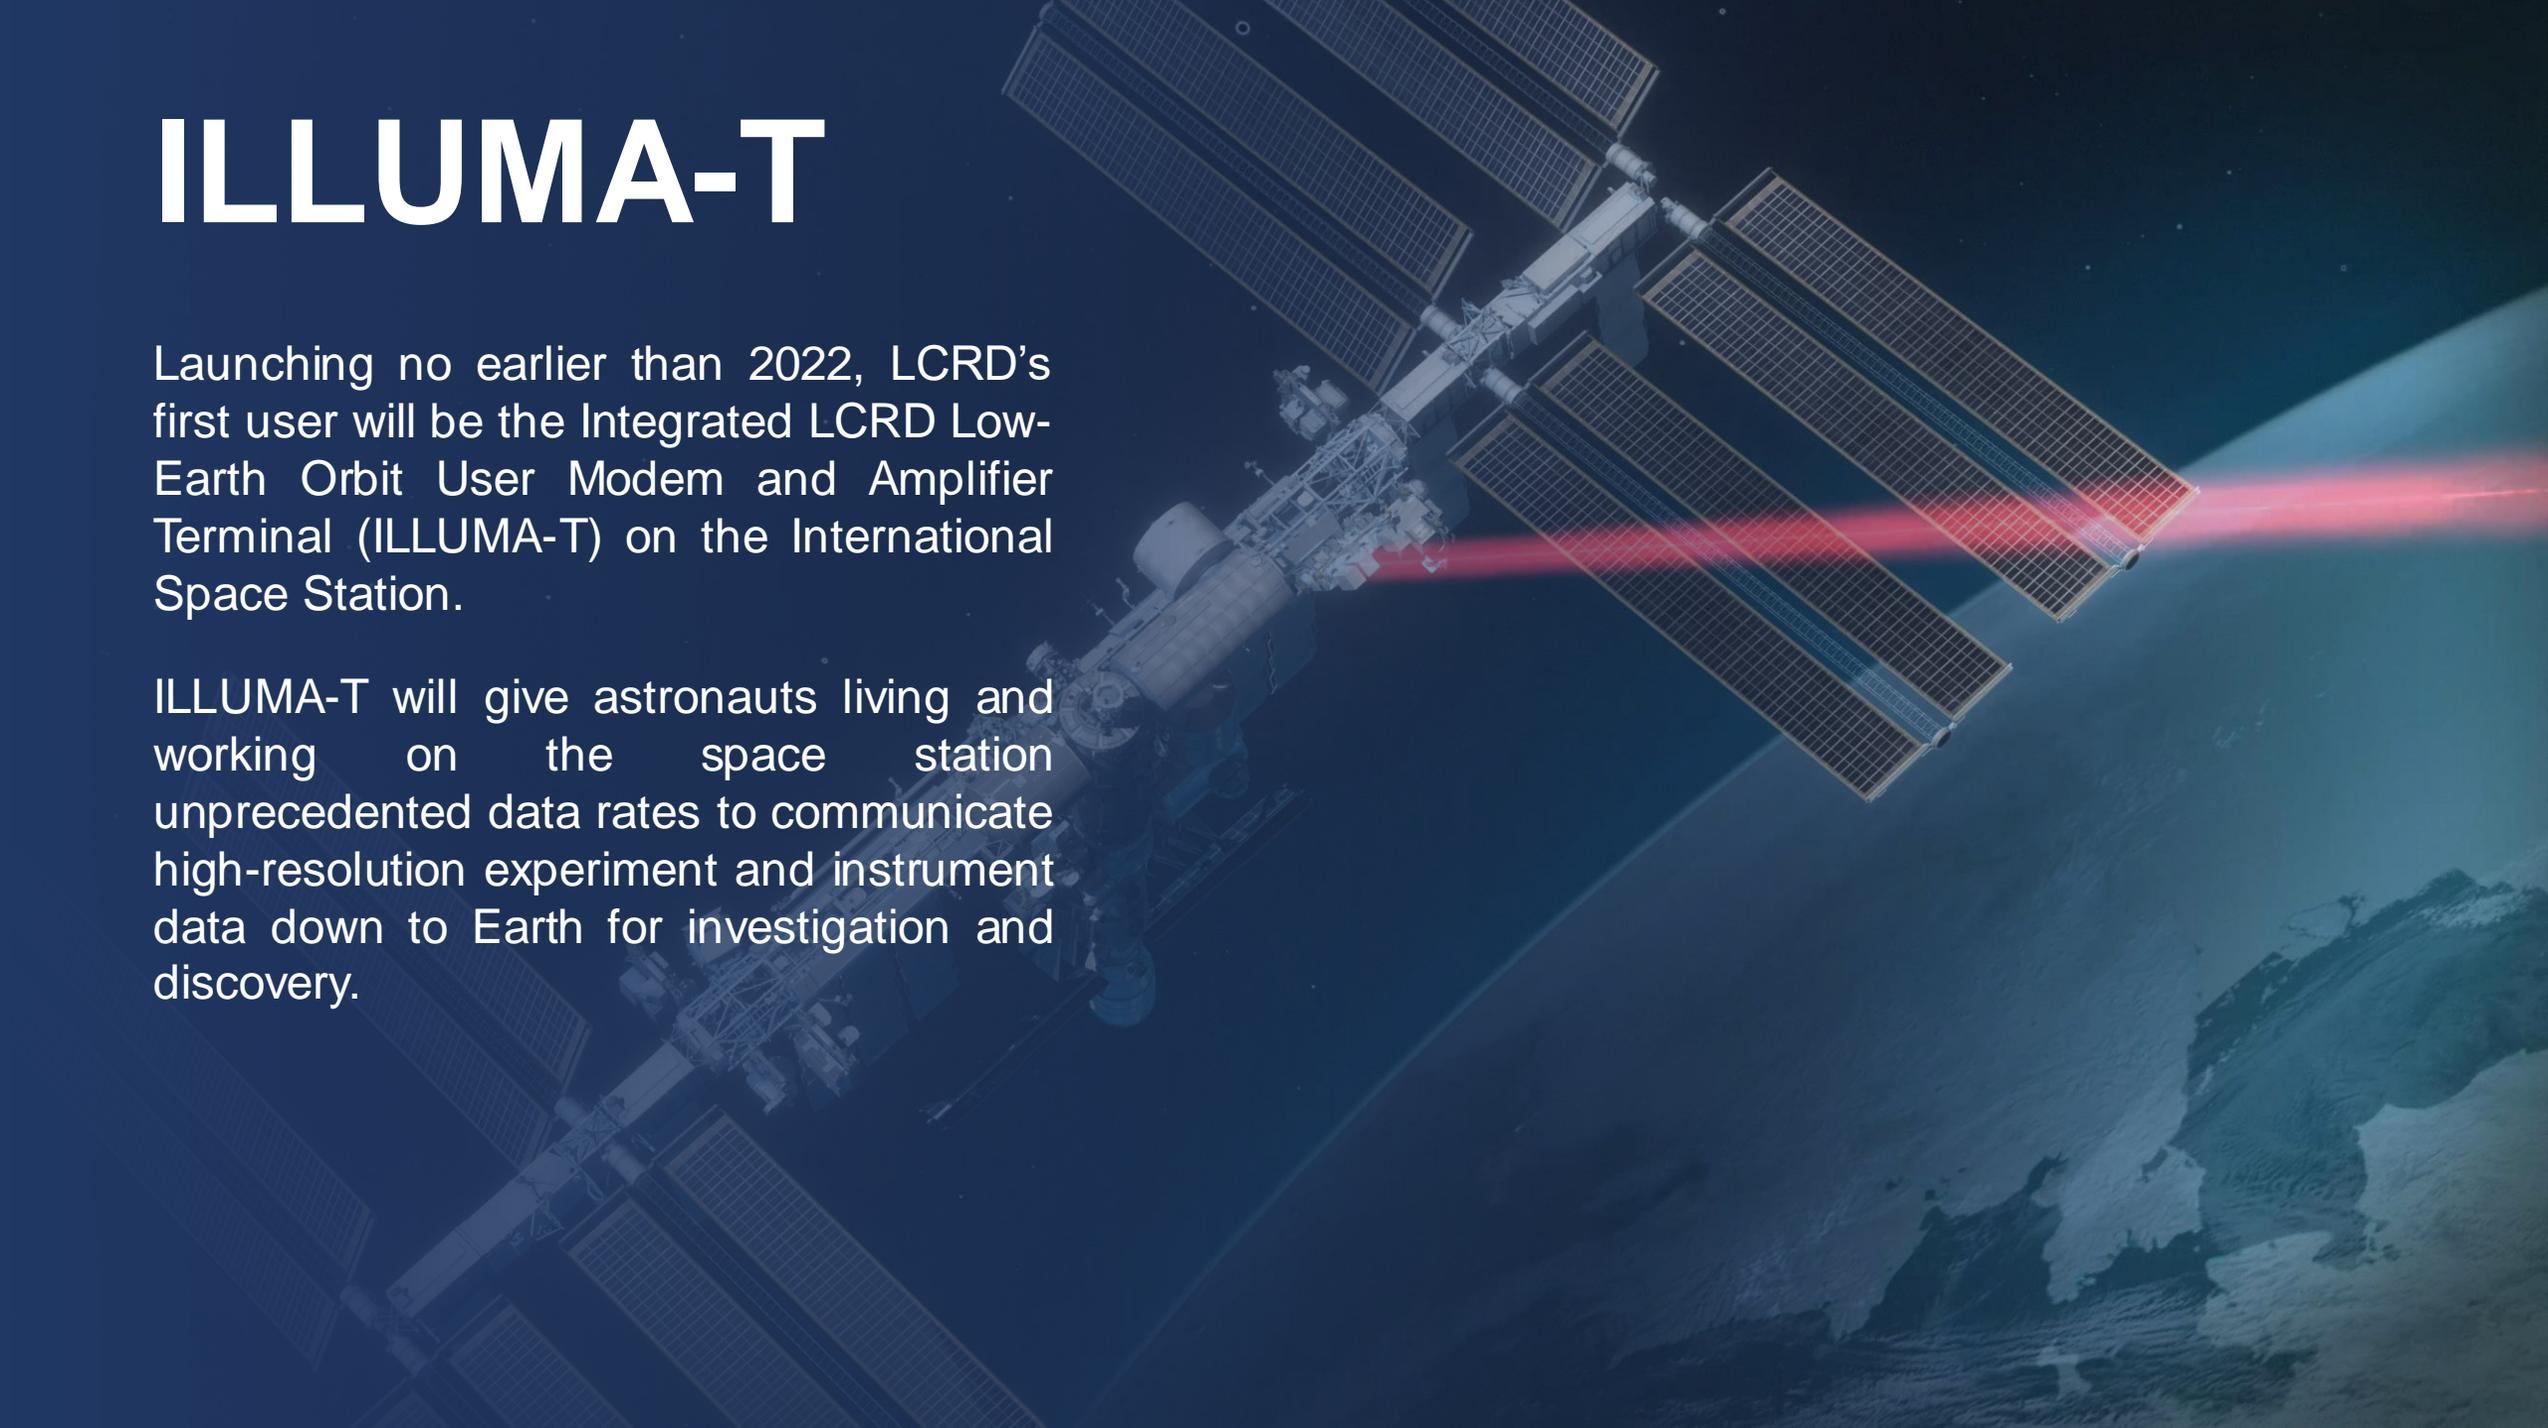

The Terabyte Infrared Delivery (TBIRD) mission is a free space high-data-rate laser communications demonstration.

Although the size of a shoebox, TBIRD will demonstrate a downlink of 200 gigabits per second - an extremely rare capability.

TBIRD is a joint mission between NASA and MIT-LL.

# ILLUMA-T

The background of the slide is a photograph of the International Space Station (ISS) in orbit above Earth. The station's complex structure, including its large solar panel arrays, is visible against the dark sky. A bright red laser beam originates from the station and extends horizontally across the right side of the frame, passing over the Earth's surface. The Earth's curvature and a portion of its blue and white surface are visible in the lower right corner.

Launching no earlier than 2022, LCRD's first user will be the Integrated LCRD Low-Earth Orbit User Modem and Amplifier Terminal (ILLUMA-T) on the International Space Station.

ILLUMA-T will give astronauts living and working on the space station unprecedented data rates to communicate high-resolution experiment and instrument data down to Earth for investigation and discovery.

# O2O

The Orion Artemis II Optical Communications System (O2O) is a laser terminal flying on NASA's second Artemis II mission.

O2O will further demonstrate that laser communications are a viable option for lunar missions.

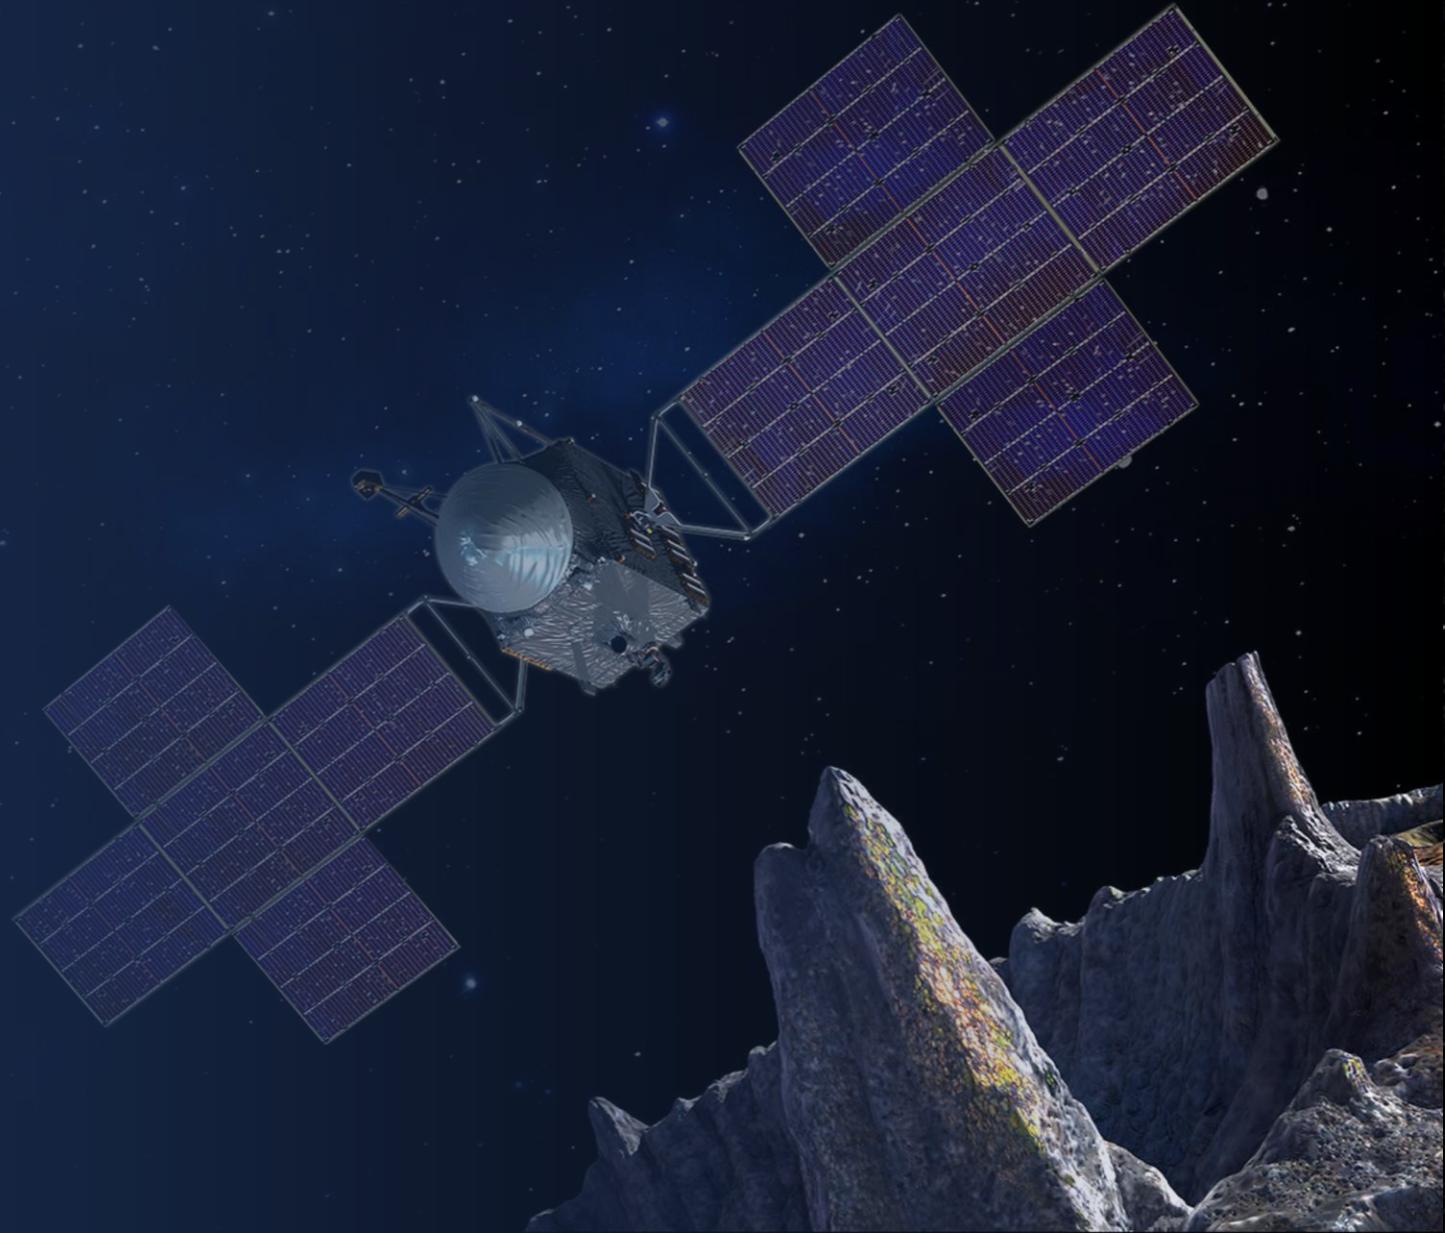

# DSOC

NASA's Psyche mission will host the Deep Space Optical Communications (DSOC) payload. Psyche is launching in 2022 and will reach its destination, the 16 Psyche asteroid, in 2026.

The DSOC payload will test laser communications technologies against the distinctive challenges presented by deep space exploration.

NASA's Jet Propulsion Laboratory leads DSOC development.

A futuristic lunar lander or communication station is shown in space. The station has a central cylindrical body with various modules, solar panels, and antennas. It is set against a dark blue background with stars, a large Earth on the left, and a smaller Moon on the right.

# Future Exploration

Through the Artemis program, NASA plans to establish humanity's presence on the Moon, and laser communications will play a vital role.

NASA is developing LunaNet, a lunar communication and navigation architecture that will use radio frequency and laser communications to give missions internet-like capabilities on the Moon.

# Watch LCRD Launch!

On November 22, 2021, NASA's LCRD will blast off to space and show the world the benefits of laser communications!

Follow along and watch the launch live on NASA TV and [nasa.gov/live](https://www.nasa.gov/live).
