DECEMBER 2004

CERTIFICATION

The enclosed document was prepared, and is being submitted, in accordance with the requirements of the Administrative Agreement On Consent between the United States Environmental Protection Agency and the National Aeronautics and Space Administration [U.S. EPA Docket Number RCRA-03-2004-0201TH].

I certify that the information contained in or accompanying this document is true, accurate, and complete.

I certify under penalty of law that this document and all attachments were prepared in accordance with procedures designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, or the immediate supervisor of such person(s), the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fines and imprisonment for knowing violations.

EXECUTIVE SUMMARY

This Supplemental Remedial Investigation (RI) has been prepared for the National Aeronautics and Space Administration (NASA) under Contract Task Order (CTO) 848 issued by the Engineering Field Activity Northeast (EFANE) of the Naval Facilities Engineering Command under the Comprehensive Long-Term Environmental Action Navy (CLEAN III) contract number N62467-94-D-0888. The supplemental RI addresses the Waste Oil Dump (WOD) Site at the NASA Goddard Space Flight Center (GSFC) Wallops Flight Facility (WFF) located in Accomack County, Virginia. The supplemental RI activities and this report have been prepared as part of the NASA environmental restoration program under the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA), as amended by the Superfund Amendments and Reauthorization Act (SARA) of 1986, and Virginia Administrative Code Hazardous Waste Management Regulations, 9 VAC20. The supplemental RI was conducted in accordance with the Final Work Plan for Supplemental RI Activities approved and finalized in January 2003 (TtNUS, 2003a).

PURPOSE

The primary scope of the Supplemental RI was to perform further investigations and evaluations of the WOD site to ensure that appropriate remedial alternatives are developed and evaluated. The development and evaluation of remedial alternatives require an understanding of the site characteristics, the nature and extent of contamination, and the identification of potential exposure pathways and receptors. As described in the final work plan, the scope of the supplemental RI included the performance of additional investigations to fill data gaps and provide supplemental data to refine the risk assessments, support engineering evaluations, and provide data needed to develop remedial alternatives for the WOD site.

The specific Supplemental RI objectives include but are not limited to the following:

- Characterization of surface and subsurface conditions throughout the study area.
- Characterization of adjacent marshland soil conditions.
- Characterization of groundwater conditions.
- Collect data to support the evaluation of natural attenuation processes potentially occurring within the aquifer.
- Further refinement of the Conceptual Site Model.
- Assessment of potential human health and environmental risks.

BACKGROUND

WFF is located in Accomack County on the Eastern Shore of the Commonwealth of Virginia. The facility is comprised of three separate areas: the Main Base (MB), the Mainland (ML), and Wallops Island (WI). These three areas are in close proximity to each other and total approximately 5,000 acres of landmass and 1,000 acres of marshland. The most heavily developed area is the MB (about 1,900 acres) that includes administrative and technical offices, tracking and data acquisition components, the range control center, rocket motor storage and processing facilities, research and development facilities, airfield and control tower, aircraft hangars and maintenance facilities, and Navy administration and housing areas.

The WFF is located in the Atlantic Coastal Plain Physiographic Province and is underlain by a thick sequence of approximately 7,000 feet of unconsolidated sediments that unconformably overlie crystalline bedrock. The principal water-bearing units beneath the WFF are, in stratigraphically descending order, the Pleistocene-age Columbia Group and three hydraulically isolated aquifer units within the underlying Miocene-age Yorktown Formation. The Columbia Group extends to a subsurface depth of approximately 60 feet and consists of interbedded sands, gravels, and sandy clays deposited under fluvial and marine conditions. The water table beneath the WFF typically occurs under unconfined conditions within the Columbia Group at depths of 0 to 30 feet. Groundwater flow directions within the Columbia, as is generally the case with most shallow unconfined aquifers, reportedly mimics the general surface topography. The Yorktown Formation is approximately 1,000 feet thick and consists of alternating sequences of fine- to coarse-grained glauconitic sands (that may be variably clayey, silty, or shelly) and finer-grained silts and clays. The sands comprise the dominant aquifers, and the silts and clays form aquitards that create confining conditions and that separate the Yorktown Formation into three (upper, middle, and lower) aquifers. At the WFF, the upper Yorktown aquifer generally occurs at a depth of about 50 to 100 feet below ground surface and is isolated from the overlying Columbia aquifer by a clay and silt aquitard that is approximately 20 to 40 feet thick. Aquifer tests at the WFF indicate that there is no significant vertical leakage across the confining unit separating the upper Yorktown aquifer from the overlying Columbia Group. The WFF and the surrounding communities rely on groundwater, primarily from the Yorktown formation, for drinking water supplies.

The WOD is located at the northern end of Runway 17-35 on a peninsula-like feature adjacent to Little Mosquito Creek. The site is currently a field vegetated with grasses, shrubs, and bushes. The southern half of the site, bordered by the active runway, is relatively flat with little slope. The central portion of the site gently slopes to the north. The northern, eastern, and western boundaries of the site are formed by steep slopes that direct non-infiltrated surface runoff into low-lying marshes that border an unnamed tributary to Little Mosquito Creek and Little Mosquito Creek. There are no surface water bodies within or immediately adjacent to the disposal areas at the WOD. The closest body of water is the narrow

unnamed tributary to Little Mosquito Creek located about 160 feet west of the site. Approximately 300 feet of marshland to the north and east of the site separate the WOD from Little Mosquito Creek.

The WOD was reportedly used for the disposal of waste oils and possibly solvents for a period from the 1940s through the 1950s. Reportedly, the site was used to dispose of excess waste oil that could not be used for fire training activities at the Former Fire Training Area (FFTA) site. No records are available to determine the types and quantities of materials disposed or the duration of this activity at the site. A review of aerial photographs from 1943 through 1994 indicate the presence of ground scarring and possible excavations in the WOD area from 1943 through 1961.

Environmental investigations began at the WOD in 1986. In 1986, the Commonwealth of Virginia conducted an inspection of the WOD and identified the presence of waste (reported as waste oils) on the surface of the site. Following further inspection and consultation, NASA conducted a removal action in the area in December 1986 including the excavation and removal of approximately 180 cubic yards of impacted soils in four separate areas of the site. No samples were collected for analysis during or after the excavations.

A preliminary assessment (PA) and site investigation (SI) of the WOD were conducted from 1988 through 1992. The studies included the performance of soil gas surveys and surface and subsurface soil and groundwater sampling and analysis. The data from these investigations indicated that no waste materials remained at the site and it was concluded that no further action was required.

No additional work was completed at WOD until 1997. In 1997, a monitoring well (WFF15-GW7) was installed and sampled within the WOD as part of an RI being conducted at an adjacent site (Site 15). The analytical results from the well sample revealed the presence of volatile organic and petroleum compounds. In response to this finding, NASA conducted an inspection of the WOD and identified an area of stained soil and stressed vegetation surrounding the newly installed well. An RI was conducted at the WOD from 1998 through 2000 and included a review of historical data, the performance of a geophysical survey, the installation and sampling of temporary monitoring wells, sampling of surface and subsurface soils, and the installation and sampling of permanent monitoring wells. The RI focused on the area of stained soil and did not investigate the remaining portions of the WOD. Surface soil samples collected from within the stained area indicated the presence of elevated concentrations of polyaromatic hydrocarbons (PAHs), primarily benzo(a)pyrene. Subsurface soils collected at the soil/water interface from immediately beneath the stain contained elevated concentrations of benzene, toluene, ethylbenzene, and xylene (BTEX) compounds and PAHs. Groundwater samples were collected over a 3-year period from monitoring wells located upgradient, within, and downgradient of the stained soil. Analytical results indicated BTEX, PAH, and metals contamination in the groundwater immediately

beneath the stained soils. Samples from monitoring wells upgradient and downgradient of the stained soil did not show significant contamination.

Based on historical records and the available analytical and groundwater level results, it was concluded in the RI that past waste oil disposal activities at the WOD were the source of a limited groundwater contamination plume. Groundwater in the area occurs in an unconfined water table aquifer within the Columbia Group that is assumed to be isolated by an aquitard from the lower Yorktown Formation. A groundwater divide was interpreted to exist at the WOD, and groundwater was projected to flow in a northwesterly and northeasterly direction from the crest of the site. Groundwater measurements and subsequently projected groundwater contours indicated that the water table was relatively flat with no steep gradients. The groundwater plume, consisting of organic and metal contaminants, appeared to be fairly stable and located immediately beneath and/or slightly downgradient of the stained soil area.

SUPPLEMENTAL 2003 RI FIELD ACTIVITIES AND FINDINGS

The scope of the Supplemental RI field investigations included collecting and analyzing surface and subsurface soil samples from throughout the WOD site, collecting and analyzing surface soils from the marsh surrounding the site, installing additional monitoring wells, and sampling the new and existing monitoring wells to better define the groundwater flow and contaminant migration pathway.

A total of 27 surface and subsurface soil samples were collected from the WOD site and analyzed for VOCs, semi-volatile organic compounds (SVOCs), polychlorinated biphenyl (PCBs), and target analyte list (TAL) metals. Additionally, surface soil samples were analyzed for pH, total organic carbon (TOC), and grain size. An additional twelve surface soil samples were collected from the marsh surrounding the WOD site and analyzed for VOCs, SVOCs, PCBs, TAL metals, pH, TOC, and grain size.

Three new monitoring wells were installed at the WOD. The purpose of the new wells was to fill data gaps to provide a more complete delineation of groundwater flow patterns (by providing additional hydraulic head data) and a more complete delineation of the nature and extent of groundwater contamination. The wells were screened across the water table to monitor for the possible presence of floating or free product. The well borings were lithologically logged to further investigate hydrogeologic conditions at the WOD, and water level measurements and groundwater samples were collected and analyzed from the new and existing wells. Groundwater samples were analyzed for VOCs plus methyl tert-butyl ether (MTBE), SVOCs, PCBs, TAL total and dissolved metals (field-filtered), and monitored natural attenuation (MNA) parameters (hydrogen, soluble manganese, nitrate, chloride, sulfate, methane/ethane/ethene, and TOC). Additionally, field parameters (for example, pH, temperature, dissolved oxygen, oxygen reduction potential (ORP), salinity, conductivity, turbidity, alkalinity, ferrous iron, and hydrogen sulfide) were measured at each well.

The analytical data from the Supplemental RI were validated in accordance with EPA Region 3 and national functional guidelines and were evaluated along with the historical RI data to further define the nature and extent of contamination at the WOD. In addition, the lithological logs from the new and existing wells and the hydraulic head data collected during the Supplemental RI were evaluated to further refine the conceptual site model. The results and findings of the evaluation are presented and discussed in this report. The major findings and conclusions of the Supplemental RI are as follows:

- The lithologic unit immediately underlying the site, the Columbia Group, consists chiefly of fine- to medium-grained sands, with lesser amounts of silt and clay.

- A silty clay layer, approximately one- to two-feet thick, exists within the Columbia Group beneath the WOD at a subsurface elevation near sea level. This clay lens may have at least a semi-regional extent and functions as a leaky aquitard that hydraulically divides the Columbia aquifer into upper and lower units.

- The clay lens within the Columbia Group appears to be absent at well location WFF15-GW7. The clay lens was encountered at adjacent and nearby borings but its presence was not noted on the boring log for this well.

- Groundwater flow in the upper unit of the Columbia aquifer beneath the WOD is in directions ranging through an arc of approximately 180 degrees, or from nearly due west, through northward, to nearly due east. This flow is consistent with the directions that are predicted from the surface topography of the WOD, which is located on a small peninsula that extends northward from the end of Runway 17-35 towards Little Mosquito Creek and its associated lowlands and wetlands.

- The measured vertical hydraulic gradient within the shallow Columbia aquifer at the WOD is downward throughout the majority of the site but shifts to horizontal and possibly an upward gradient in the lowlands surrounding the site itself. The vertical gradients indicate that the area of higher elevation is a groundwater recharge area and the lowland areas are a groundwater discharge area.

- The unnamed tributary may be a discharge point for a small component of shallow groundwater flowing westward from the WOD. Little Mosquito Creek is expected to be the significant groundwater discharge point for the study area.

- Contamination at the WOD exists in both the soil and groundwater medium, but the extent of contamination is generally localized and concentrated in two geographic areas:

- A localized zone of fill material was identified in the west-central portion of the site. Samples from the fill material contained elevated concentrations of metals and some organic compounds, primarily PAHs and BTEX components. The limited presence to absence of groundwater contamination immediately downgradient of the area of fill indicates that this fill material is not significantly impacting the quality of the local groundwater.

- A localized area of contamination, in the vicinity of monitoring well WFF15-GW7, exists beneath the stained soil area identified in the 2001 RI. Subsurface soil samples collected from the soil/groundwater interface (23 to 24 feet below the ground surface) contained elevated concentrations of some metals and many organic compounds, primarily PAHs and BTEX compounds. Relatively low levels of contamination were encountered at the surface, and the intervening soil horizons were relatively free of contamination. Similarly, soil samples and borings from upgradient and nearby areas were relatively free of contamination. The contamination pattern suggests that waste materials may have been buried at this location.

- Groundwater contamination at the WOD is very localized and is centered in the vicinity of monitoring well WFF15-GW7. The Supplemental RI and historical sampling of this well has indicated that significant metals, BTEX compounds, and PAH contamination exists at this location. In addition, a floating layer of petroleum product (0.4 foot thick) was measured in this well at the start of the Supplemental RI field activities. The presence of a free-phase product and the high concentrations of contamination detected in the dissolved phase within the groundwater indicate that the contaminant source occurs at or near the water table in the immediate vicinity of WFF15-GW7.

- The contaminated groundwater associated with well WFF15-GW7 is not migrating for significant distances from the immediate vicinity of the apparent source. Available data indicate that the groundwater plume emanating from this source area migrates downward within the aquifer but attenuates rapidly in the downgradient direction. Very low concentrations of a few VOCs and no SVOCs were detected in the downgradient deep well, and no organic compounds at all were detected in the downgradient shallow well.

- The presence of the low-level contaminant plume in the deep downgradient well, which is screened below the expected depth of the clay lens, and the absence of the plume in the shallow downgradient well, appear to confirm the observation that the clay lens is not present in the immediate vicinity of the source area.

- Available data suggests that the attenuation and limited migration of the contaminant plume is related to the immobile nature of many of the contaminants and the active biodegradation (evidenced by nearly depleted oxygen levels, elevated methane levels, and a reducing environment) that is occurring at the source area. In addition, it is likely that the multiple excavations that have occurred at the WOD have created a heterogeneous aquifer whose properties, including hydraulic conductivity, vary within short lateral distances. It is likely that areas of low hydraulic conductivity exist within the site. These areas of low hydraulic conductivity likely result in a lower groundwater velocity, which increases the opportunity for degradation over a short distance.

- Contaminant concentrations in Supplemental RI groundwater samples collected from within the localized plume are within the same order of magnitude as seen in historical samples. The presence of weathered product indicates a significant volume of source material still remains, but it appears that the various processes of biodegradation are effectively attenuating or restricting the lateral extent of the dissolved-phase plume.

BASELINE RISK ASSESSMENTS

Baseline human health and ecological risk assessments using the historical and Supplemental RI surface and subsurface soil sample analytical results and Supplemental RI groundwater sample analytical results were performed. The human health risk assessment evaluated potential risks to current and future industrial workers, future construction workers and hypothetical future residents. Because the WOD is located at the end of an active runway, access to the area is heavily restricted. These restrictions limit the current activities at the site to periodic mowing and maintenance functions. The future anticipated land use for the WOD is the continued use of the area as an airfield. The development of the area for other uses, especially residential purposes, is extremely unlikely. The residential scenario was developed as a baseline for comparison purposes in accordance with EPA guidelines. It should also be noted that for the hypothetical future resident exposure scenario it was assumed that the shallow WOD groundwater (Columbia aquifer) would be used for residential purposes. The development of the shallow aquifer as a water supply is highly unlikely in that the lower Yorktown aquifer is more productive and use of the shallow Columbia aquifer is discouraged and restricted by the Commonwealth of Virginia under a groundwater management program administered by the VADEQ. Under this program, NASA has abandoned all water supply wells that withdraw from the Columbia aquifer.

The human health risk assessment was performed in accordance with the most recent EPA and VADEQ guidance and in accordance with the procedures and methodologies described in the work plan. Estimated potential risks were calculated for the reasonable maximum exposure (RME) scenario, which represents the conservative, upper end or most reasonably assumed maximum potential exposure to

contamination at the WOD. Carcinogenic and noncarcinogenic risks were calculated. EPA and VADEQ have defined the cancer risk range of 10^{-4} to 10^{-6} as the "target range" or "acceptable risk range" for most sites evaluated under their programs. This risk range represents the potential for contaminant exposure to cause one additional case of cancer in a population of ten-thousand people to one additional case of cancer in a population of one million people. Cumulative cancer risks greater than 10^{-4} generally will indicate that some degree of remediation is required, and cancer risks less than 10^{-6} normally will not result in remedial efforts. When the calculated risk falls between10^{-4} to 10^{-6}, decisions are typically made on a case by case basis. Noncancer risks were evaluated using the Hazard Index (HI) system. EPA and VADEQ have established this system to evaluate the potential for noncarcinogenic health effects of contamination. An HI of 1.0 or less is not expected to result in adverse health effects. The HI for an exposure scenario and for specific target organs are both evaluated under this system. In general, if the total HI exceeds 1.0 than the specific target organs expected to be affected by the contaminants are further evaluated to determine the HI for that organ. The HI value is not a numeric indication of risk. Rather, an HI that exceeds 1.0 indicates that a noncancer health effect cannot be ruled out.

The current industrial worker risk scenario represents the current and likely future exposure scenario for the WOD. This risk scenario assumes an industrial worker will be exposed to surface soils or subsurface and surface soils through the performance of limited routine maintenance and mowing activities at the WOD. The cancer risk for exposure to surface soils under this scenario was calculated to be 2.7×10^{-7}. This represents about 3 additional cases of cancer in a population of ten million people, which is less of a risk than the lower end of the EPA acceptable risk range, one case in one million. There were no contaminants detected that would contribute to a noncancer health effect. For potential exposure to subsurface and surface soils, assuming that subsurface soils were disturbed and became available as surface soils, the cancer risk was calculated as $2.1 \times 10^{-7.}$ This risk is also less than the acceptable risk range (10^{-4} to 10^{-6}) and represents a risk of about 2 cases in ten million industrial workers. The total and all target organ noncancer risks were found to be below an HI of 1.0.

The future industrial worker scenario was developed to assess the potential risks to industrial workers if the runway were to become inactive and the WOD was maintained under typical programs requiring more frequent mowing and maintenance activities as are currently being conducted for similar areas at WFF. The cancer risk resulting from exposure to surface soils and total soils (surface and subsurface combined) was calculated as 1.7 and 1.4×10^{-6}, respectively. These risks (between 1 and 2 in one million) are at the lower end of the acceptable risk range discussed above. Noncancer risks for both surface and total soils were found to be below an HI of 1.0.

The construction worker risk scenario was developed to assess the potential risks associated with workers being exposed to surface and subsurface soils and groundwater should the area be developed in

the future. The cancer risk for this scenario was calculated to be 2.0×10^{-7} (two in ten million) which is less of a risk than the lower end of the acceptable risk range (one in one million). All noncancer risks were calculated as having an HI of less than 1.0.

The future residential use scenario, although not likely to occur, was developed to evaluate the potential risks associated with residents living at the WOD and using the shallow groundwater at the site for domestic purposes. Under this scenario it was assumed that subsurface and surface soils would be available for contact and that no soil remediation would be performed and that groundwater would not be treated before use. It was also assumed that a resident would be exposed to the same contaminant levels found at the site from childhood through adult life for a period of 30 years. The cancer risk for this scenario was calculated to be 4.3×10^{-4} (about 4 in ten thousand) which is a greater risk than the high end of the acceptable risk range (1×10^{-4} or one in ten-thousand). The risks greater than the acceptable risk range were almost exclusively associated with hypothetical ingestion of untreated groundwater (4.25×10^{-4}). The primary risk driver was arsenic in groundwater. Tetrachloroethene and benzene also contributed to the groundwater risk. Total lifetime soil cancer risks were calculated as 7.3×10^{-6}. Potential noncancer health effects for exposure to soils under the residential use scenario were calculated as having an HI of less than 1.0 for both the child and adult receptor. However, an evaluation of the potential domestic use of untreated site groundwater resulted in HIs greater than 1.0 based primarily on potential exposure to arsenic, iron, manganese, aluminum, and 4-methylphenol in drinking water and naphthalene in shower vapors.

Arsenic was detected in only the deep monitoring (WFF16-GW2D) well located immediately downgradient of the source area. As discussed above, data indicate that groundwater conditions in this area reflect a highly reducing environment. Because of the reducing conditions in this area, it is not known if the presence of arsenic in this single sample is indicative of a waste constituent or if the reducing environment has enhanced the dissolution of arsenic from the geologic materials. Tetrachloroethene was also detected in only one monitoring well, WFF15-GW7. The concentration of tertachloroethene (5 ug/L) in the single sample was equal to the Maximum Contaminant Limit (MCL), (the maximum concentration permitted in public drinking water supplies), for tetrachloroethene. Benzene was detected in only these same two wells (WFF16-GW2D and WFF15-GW7) located in the source area. Both detections exceeded the MCL for benzene (5 ug/L). Floating petroleum product was present at monitoring well WFF15-GW7 and the sample from this well showed the highest number and levels of contamination at the WOD.

An ecological risk assessment was performed to determine whether adverse ecological impacts are present as a result of exposure to contaminants released to the environment at the WOD. The habitat, contaminants present, migration pathways, and the routes that receptors may be exposed to contaminants at the WOD were defined and evaluated as part of the assessment. The WOD is a

terrestrial habitat and the receptors evaluated for the terrestrial environment were plants, soil invertebrates, and herbivorous and insectivorous birds and mammals. In addition to considering the terrestrial environment, the ERA also evaluated the risks to benthic invertebrates (aquatic life) that may be exposed to contaminants that migrated from the WOD to marsh soils or sediments in the surrounding area. The contaminant concentrations, occurrence, distribution and potential effects data were evaluated to determine whether adverse effects to growth, survival, and reproduction were likely to occur in these receptors due to exposure to contaminants identified at the WOD. Overall, risks to plant, terrestrial wildlife, and terrestrial and benthic invertebrates from chemicals detected at the WOD were found to be low to negligible.

1.0 INTRODUCTION

This Supplemental Remedial Investigation (RI) has been prepared for the National Aeronautics and Space Administration (NASA) under Contract Task Order (CTO) 848 issued by the Engineering Field Activity Northeast (EFANE) of the Naval Facilities Engineering Command under the Comprehensive Long-Term Environmental Action Navy (CLEAN III) contract number N62467-94-D-0888. The Supplemental RI addresses the Waste Oil Dump (WOD) Site at the NASA Goddard Space Flight Center (GSFC) Wallops Flight Facility (WFF) located in Accomack County, Virginia. The Supplemental RI activities and this report have been prepared as part of the NASA environmental restoration program under the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA), as amended by the Superfund Amendments and Reauthorization Act (SARA) of 1986, and Virginia Administrative Code Hazardous Waste Management Regulations, 9 VAC20. The Supplemental RI was conducted in accordance with the Final Work Plan for Supplemental RI Activities approved and finalized in January 2003 (TtNUS, 2003a).

1.1 SCOPE AND OBJECTIVES

The primary scope of the Supplemental RI is to perform further investigations and evaluations of the WOD site to ensure that appropriate remedial alternatives are developed and evaluated. The development and evaluation of remedial alternatives require an understanding of the site characteristics, the nature and extent of contamination, and the identification of potential exposure pathways and receptors. As described in the final work plan, the scope of the Supplemental RI included the performance of additional investigations to fill data gaps and provide supplemental data to refine the risk assessments, to support engineering evaluations, and to provide data needed to develop remedial alternatives for the WOD site.

The general objectives of the Supplemental RI are to adequately characterize the WOD site and groundwater conditions at the WOD, to quantify the potential risks posed to human health and the environment as a result of exposure to those conditions, and to provide sufficient data to evaluate the need and options for remedial actions. The specific objectives include but are not limited to the following:

- Characterization of surface and subsurface conditions throughout the study area.
- Characterization of adjacent marshland soil conditions.
- Characterization of groundwater conditions.
- Evaluation of the occurrence and/or potential for natural attenuation of contaminants.
- Further refinement of the Conceptual Site Model (CSM).
- Assessment of potential human health and environmental risks posed by site contaminants.

1.2 PLAN ORGANIZATION

This report presents a review of historical and current information and analytical data pertinent to the WFF and the WOD site and presents a technical evaluation of that data. Section 1.0 provides this introduction and the scope and objectives of the Supplemental RI. Section 2.0 provides a summary of the facility background and environmental investigations. Sections 3.0 reviews the WOD operational and investigation history and CSM, and summarizes the planned Supplemental RI field activities. Section 4.0 presents a discussion of the Supplemental RI activities conducted. Section 5.0 discusses the historical data, presents the results of the Supplemental RI field sampling activities, evaluates the nature and extent of contamination, and refines the CSM. The properties that affect the fate and transport of the contaminants identified at the WOD are discussed in Section 6.0. Sections 7.0 and 8.0 assess the human and ecological risks associated with potential exposure to contaminants at the WOD.

2.0 FACILITY BACKGROUND AND HISTORY

2.1 FACILITY DESCRIPTION

2.1.1 Facility Location

WFF is located in Accomack County on the Eastern Shore of the Commonwealth of Virginia (Figure 2-1). The facility is comprised of three separate areas: the Main Base (MB), the Mainland (ML), and Wallops Island (WI). These three areas are in close proximity to each other and total approximately 5,000 acres of landmass and 1,000 acres of marshland. The most heavily developed area is the MB (about 1,900 acres) that includes administrative and technical offices, tracking and data acquisition components, the range control center, rocket motor storage and processing facilities, research and development facilities, an airfield and control tower, aircraft hangars and maintenance facilities, and Navy administration and housing areas. The WOD is located within the MB area (Figure 2-2).

2.1.2 Facility History

NASA has had a presence in the WFF area since the mid-1940s. From the 1940s until 1959, NASA's predecessor organization, the National Advisory Committee for Aeronautics (NACA), had a limited presence on Wallops Island. In 1959, shortly after its creation, NASA acquired the MB from the Navy. The Navy operated an aviation training field at the MB area from 1942 through 1958. NASA also acquired the ML area at this time and continued to expand land purchases on WI. In 1960, a causeway was constructed from the ML to WI. A detailed history of land ownership and transfers is presented in the Environmental Resources Document, NASA GSFC WFF Wallops Island, Virginia, October 1999, prepared by Occu-Health, Inc. (Occu-Health, 1999).

Beginning in 1942, the Navy operated a training airfield at the MB area, the Chincoteague Naval Auxiliary Air Station, prior to NASA occupation in 1959. The Navy constructed runways, buildings, and other support facilities throughout the MB area in 1943. The facility was used for naval aviation training until 1959 when operations ceased and the property was transferred to NASA. In addition to aviation training, the Navy used the facility for aviation ordnance testing to develop and test aviation ordnance and guided missiles [US Army Corps of Engineers (USACE), 2000].

NASA continues to maintain the runways constructed at the facility by the Navy and occupies many of the structures and buildings that were present at the time of the property transfer. In addition, NASA has expanded and constructed additional buildings within the MB area to support their mission and to provide support to other tenant organizations. The mission of NASA's WFF has undergone several changes

since it was established in 1959, but the main focus has been and continues to be rocket research, the management of suborbital projects, suborbital and orbital tracking, aeronautical research, and space technology research. NASA WFF also provides support to other tenant organizations including the Navy, which maintains surface combat systems and ship systems engineering training centers, and uses the airfield and launch sites at WFF. Other tenant organizations include the National Oceanic and Atmospheric Administration (NOAA), which maintains facilities at the MB, the United States Coast Guard, and the Mid-Atlantic Regional Spaceport, which utilizes the launch and rocket support facilities (NASA, 2002).

2.2 FACILITY ENVIRONMENTAL INVESTIGATION HISTORY

Formal environmental investigations on a facility-wide basis began at WFF in 1988 with the initiation of an environmental site survey. This survey was conducted for NASA by Ebasco Services, Inc. between 1988 and 1990 and resulted in the identification of 15 areas considered to be potential sites (Metcalf & Eddy, Inc., 1996). Ten of these sites were located at the MB, and the other five were located on WI. A series of initial investigations at those sites culminated in the publishing of a Site Inspection Report in 1992 that was later finalized in 1996 (Metcalf & Eddy, Inc., 1996). The Site Inspection Report details the activities and findings for each site. In general, the investigations included the performance of background document reviews, magnetometer studies, soil gas surveys, sampling of soils, groundwater, surface water, and sediments, and the preparation of preliminary Hazard Ranking System scores.

As a result of the site inspection, individual sites were prioritized for additional studies and evaluation. Since 1992, sites have been pursued on individual tracks based on the priority and potential hazard identified. Actions conducted at these sites include supplemental investigations, sampling programs, removals, product recovery, RIs, feasibility studies (FSs), remediation, and closeout. In addition to the formal facility-wide environmental assessment and site inspection process, NASA has conducted other environmental assessments and cleanup programs throughout the facility. The Virginia Department of Environmental Quality (VADEQ) has provided monitoring and regulatory support throughout this process. The WOD has been the subject of removal actions and ongoing investigations including an RI, focused groundwater investigations, and this Supplemental RI.

Environmental investigations at the WOD began in 1986 after a Commonwealth of Virginia inspection noted the presence of possible waste oil in surface soils at the site. NASA responded to this finding by conducting a soil excavation and disposal in that same year. In 1988, a preliminary assessment of the area was conducted. As a follow-up to the preliminary assessment, a site inspection including soil, groundwater, and sediment sampling and a soil gas survey was conducted in 1989. Based on the results of the soil gas study, additional surveys and sampling were conducted in 1990. Based on these

investigations, it was concluded that no further action was necessary at the WOD. During the performance of an RI at an adjacent site (Site 15 Debris Pile), groundwater contamination was discovered that was suspected to be originating from the WOD area. Upon further investigation, a previously unknown area of surface disposal was discovered at the WOD. In response to this finding, an RI was initiated at the WOD in 1998 and completed in 2000. Section 3.0 of this report provides a more detailed history of the WOD, summarizes the analytical findings from previous investigations, and reviews the planned Supplemental RI activities.

2.3 FACILITY ENVIRONMENTAL SETTING

2.3.1 Facility Topography and Drainage

WFF is located on the eastern shore of the Delmarva Peninsula and is relatively flat with no major topographic features. Numerous inlets, tidal estuaries, marshes, bays, and creeks exist throughout the WFF area. The MB is relatively flat with a reported maximum elevation of about 40 feet above mean sea level (msl) (Occu-Health, Inc., 1999). The MB is bordered to the east by extensive marshland and creeks that drain to the Chincoteague Bay and inlet. Little Mosquito Creek, which eventually also flows east into the inlet and to the Atlantic Ocean, borders the MB to the north and west. State Routes 175 and 798 form the southern and southeastern borders of the facility (see Figure 2-2). The runway complex covers a large portion of the MB and forms a flat plateau-like feature that covers the majority of the highest elevations at MB.

Surface water drainage from the MB is through natural and man-made drainage structures. Drainage within the industrialized portions of the MB is controlled and diverted by stormwater collection and conveyance systems. In addition, portions of the base have been isolated from surface water drainage areas by the formation of berms and higher elevation structures. The natural drainage patterns for the southwestern, western, and northern portions of the MB are to Mosquito Creek and its tributaries. The eastern, southeastern, and southern portions of the MB drain to a series of marshlands, creeks, and bays that lead to Chincoteague Bay and the Atlantic Ocean.

Surface waters in the vicinity of the MB are categorized as Class II (Estuarine Waters) according to the Commonwealth of Virginia Water Quality Standards (9 VAC 25-260). The larger, low-lying, receiving waters of the area are tidally influenced and are brackish to saline.

Wetlands are numerous in the WFF vicinity. The open water areas adjacent to and within WFF are mostly bordered by wetlands that fall into three categories: marine, estuarine, and palustrine. Marine and estuarine wetlands are tidal wetlands, and palustrine wetlands can be tidal or nontidal. Wetlands in the

area of WFF are delineated by the Accomack County Wetlands Board, the Commonwealth of Virginia, and the USACE (Occu-Health, Inc., 1999).

2.3.2 Facility Soils

Soils at WFF are coastal plain soils that are typically nearly level, very deep, and well drained. Soils within upland, terrace, and level portions of the MB area are predominately Bojac fine sandy loam [US Department of Agriculture (USDA), 1994] (see Figure 2-3). This soil type is reported to be a low organic content, acidic, well-drained soil with moderately rapid permeability. The more steeply sloped areas around the perimeter of the MB and the slopes leading from the level areas to the marshlands are predominantly classified as Molena loamy sand. These soils have properties similar to the Bojac series but reportedly have a higher permeability and are more acidic. Other identified soil types include silty loams and mucky sandy loam (Chincoteague and Polawana series) that occur within the marshland areas around the outer perimeter of the MB.

2.3.3 Area General Hydrogeology

The WFF is located in the Atlantic Coastal Plain Physiographic Province and is underlain by a thick sequence of approximately 7,000 feet of unconsolidated sediments that unconformably overlie crystalline bedrock. The sediments range in age from Recent to Cretaceous and generally consist of alternating series of sands, silts, clays, and gravels. The individual geologic units dip gently to the southeast at a rate of approximately 20 to 80 feet per mile (less than 1 degree) and also thicken in the downdip direction, creating a wedge-shaped section of sediments that gradually thin westward to their updip limit of extent at the Fall Line.

The principle water-bearing units beneath the WFF are, in stratigraphically descending order, the Pleistocene-age Columbia Group and three hydraulically isolated aquifer units within the underlying Miocene-age Yorktown Formation [United States Geological Survey (USGS), 1968]. Collectively, these units form the four major aquifers on the Eastern Shore of Virginia (as identified by the VADEQ) and locally are the primary source of water for public and domestic supplies and for agricultural and industrial uses (Occu-Health, Inc., 1999).

The Columbia Group extends to a subsurface depth of approximately 60 feet and consists of interbedded sands, gravels, and sandy clays deposited under fluvial and marine conditions. The Columbia Group is overlain by a variably thin (generally about 5 feet) veneer of recent deposits composed chiefly of wind-deposited or fluvial sands, silts, and gravels. Groundwater beneath the WFF typically occurs under unconfined conditions within the recent deposits and Columbia Group at depths of 0 to 30 feet (Occu-

Health, Inc., 1999). The water table, as is generally the case with most shallow unconfined aquifers, reportedly mimics the general surface topography. Aquifer tests conducted at the WFF indicate that the hydraulic conductivity of the Columbia Group ranges from about 80 to 200 feet per day, and the specific yield of these deposits ranges from about 0.01 to 0.13 (Occu-Health, Inc., 1999).

The Yorktown Formation is approximately 1,000 feet thick and consists of alternating sequences of fine-to coarse-grained glauconitic sands (that may be variably clayey, silty, or shelly) and finer-grained silts and clays (USGS, 1968; Occu-Health, Inc., 1999). The sands comprise the dominant aquifers, and the silts and clays form aquitards that create confining conditions and that separate the Yorktown Formation into three (upper, middle, and lower) aquifers. At the WFF, the upper Yorktown aquifer generally occurs at a depth of about 100 feet below ground surface and is isolated from the overlying Columbia aquifer by a clay and silt aquitard that is approximately 20 to 40 feet thick. Aquifer tests conducted at the WFF indicated that the transmissivity ranges from about 8,500 to 14,500 gallons per day per foot for the upper aquifer to 4,000 gallons per day per foot for the middle aquifer, and the storativity ranges from about 0.003 for the upper aquifer to about 0.002 to 0.0002 for the middle aquifer. These aquifer tests also indicated that there was no significant vertical leakage across the confining unit separating the upper Yorktown aquifer from the overlying Columbia Group.

Aquifer tests conducted at the WFF were reviewed and discussed in the Design Investigation of the Aviation Fuel Tank Farm, or AFTF (Metcalf and Eddy, 1992), to evaluate the degree to which the upper Yorktown aquitard isolates groundwater flow within the Columbia Group and prevents the downward migration of this groundwater into the underlying Yorktown aquifer. This evaluation was performed to satisfy a request by the State Water Control Board (SWCB) for an assessment of the risk of vertical migration of shallow (Columbia Group) groundwater contamination at that site into the underlying Yorktown aquifer due to the pumping of nearby potable supply wells. A review of the design report indicates that there is no single pumping test that can confirm the hypothesis that there is no groundwater migration across the upper aquitard, but, taken as a group in combination with other published materials discussing the regional Yorktown aquifer, the studies suggest that this conclusion is correct.

The aquifer test most pertinent to this current investigation involved the pumping of former supply well D-39 (a shallow well completed in the Columbia Group) for 72 hours, and the measurement of aquifer responses in the Columbia Group and the upper Yorktown Formation in a pair of nearby monitoring wells (Metcalf and Eddy, 1992). The rate of drawdown in the Columbia Group was constant throughout the pumping period, and it was concluded that the constant drawdown (or more specifically, the absence of a reduced rate of drawdown through time) was indicative of a lack of recharge (or leakage) from the underlying Yorktown Formation.

Another test discussed in the Design Investigation (Metcalf and Eddy, 1992) suggested that leakage across the confining unit may occur, but the results from this test were highly qualified and considered inconclusive or questionable. In this test, the pumping of former supply well F-35 (completed in the upper Yorktown Formation) for 24 hours apparently induced drawdown in an adjacent monitoring well completed in the Columbia Group. However, changes in the rates of drawdown in this well were interpreted as potential interferences from the pumping of other nearby supply wells (Metcalf and Eddy, 1992). It was also noted that although the monitoring well used for this test was completed in the Columbia Group, the borehole for that well was originally drilled into the upper Yorktown Formation. From this, the investigation concluded that if local leakage across the aquitard did occur, it may have been through the breach created by the borehole.

Other aquifer tests presented in the Design Investigation report (Metcalf and Eddy, 1992) were primarily intra-Yorktown tests that demonstrated the efficacy of the Yorktown aquitards in separating the Yorktown into hydraulically isolated upper, middle, and lower aquifers. In one test, the pumping of the middle Yorktown aquifer did not induce a response in the overlying Columbia aquifer. The lack of hydraulic communication between the Middle Yorktown aquifer and the Columbia was attributed to the presences of aquitards within the Yorktown and between the Yorktown and Columbia formations. However, it could not be stated for certain that the presence of the upper aquitard alone would have produced the same effects.

Groundwater flow directions within the Columbia Group throughout the base are variable, but are consistent with the flow directions that are typical or expected for a water-table or unconfined aquifer. That is, the topography of the water table is a generally subdued reflection of the surface topography. The WFF is essentially a peninsula that is surrounded on three sides by surface water bodies that reside at an elevation of sea level and function as discharge points for groundwater, and groundwater generally flows from the facility towards these surface water bodies. As will be discussed in detail in Section 4, the WOD is also essentially a peninsula-like feature and groundwater at the WOD flows in northwesterly to northeasterly direction, toward the unnamed tributary and Little Mosquito Creek.

2.3.4 Area Water Supplies

Groundwater is the only source for drinking, agricultural, and process water within the WFF area. This is generally true for a large portion of the Eastern Shore. Because of the reliance on groundwater and the coastal proximity of the area, the Commonwealth of Virginia has declared the Eastern Shore of Virginia a Critical Groundwater Area. The withdrawal of groundwater from the area, including Accomack County, is controlled through the issuance of withdrawal permits under the Virginia Groundwater Management Act. The State Water Control Board, in consultation with local planning commissions and the Department of

Health, administers the permitting program and allocates groundwater withdrawal volumes as part of the permitting process.

WFF operates and maintains its own permitted water supply system that includes five wells actively used to withdraw water from the Yorktown Formation. The locations of the WFF MB potable supply wells are illustrated on Figure 2-4. In addition, NOAA and the Town of Chincoteague operate water supply wells located on WFF property. NOAA operates a single well drilled into the Yorktown aquifer. The Town of Chincoteague operates eight supply wells located along the eastern boundary of the WFF MB property. Three of these wells are shallow wells drilled into the Columbia aquifer and the other five wells are deeper wells installed in the Yorktown aquifer. Table 2.1 presents depth and screened interval information for the supply wells located on the MB facility.

The WFF MB supply wells are not affected by the WOD, which has locally impacted the Columbia Aquifer. As illustrated on Figure 2-4, the supply wells are all located hydraulically upgradient from the WOD, as the groundwater originating at the WOD migrates in a generally northeastward and northwestward direction and toward Little Mosquito Creek and the unnamed tributary. The supply wells are located at least 3,000 feet upgradient of the WOD, and because most of these wells withdraw water from the Yorktown Aquifer, are also vertically isolated from the WOD by the intervening upper Yorktown aquitard. The Town of Chincoteague supply wells that withdraw water from the Columbia Aquifer are located approximately 4,000 feet upgradient of the site.

3.0 WASTE OIL DUMP (WOD) BACKGROUND AND HISTORY

3.1 WOD DESCRIPTION

3.1.1 Facility Location

The WOD is located at the northern end of Runway 17-35 on a peninsula-like feature adjacent to Little Mosquito Creek (see Figure 3-1). The southern half of the site is basically flat, with little slope, and is grass covered. The central portion of the site slopes to the north and east, with slopes ranging from 1 to 3 percent. The northern, eastern, and western boundaries of the site are steeply sloped. These slopes direct non-infiltrated surface runoff into low-lying marshes that border an unnamed tributary to Little Mosquito Creek and Little Mosquito Creek. The northern portion of the site was recently clear cut of a large stand of conifer trees. Vegetation currently consists of bushes and tall grasses. Immediately to the west and southwest, the WOD is bordered by two other suspected disposal sites used by the Navy prior to NASA operations. These two sites are referred to as Debris Pile-Site 15 and Abandoned Drum Field-Site 9. Both of these sites have been designated as Formerly Utilized Defense Sites (FUDS) under federal programs and are under investigation by the USACE. There are no surface water bodies within or immediately adjacent to the disposal area at the WOD. The closest body of water is a narrow, unnamed tributary to Little Mosquito Creek located about 160 feet west of the site. Approximately 300 feet of marshland to the north and east separate WOD from Little Mosquito Creek.

3.1.2 WOD Operational History

The WOD was reportedly used for the disposal of waste oils and possibly solvents from the 1940s through the 1950s (Versar, Inc., 2001a). Reportedly, the site was used to dispose of excess waste oil that could not be used for fire training activities at the Former Fire Training Area (FFTA) site. No records are available to determine the types and quantities of materials disposed or the duration of this activity at the site. The USACE and the EPA have both conducted evaluations of historical aerial photographs that assist in defining the nature and timeframe of the use of the WOD (USACE, 2000; USEPA, 1996).

The WOD is evident as an excavated area north of Runway 17-35 in a 1943 aerial photograph (USACE, 2000). An open, less heavily vegetated and more level area is present between the runway and the suspected WOD area. As indicated in Section 2 of this report, the runway and the support structures were constructed during 1942 and 1943. Photographs from 1949 and 1954 (USACE, 2000), show a larger excavated/disturbed area at WOD with an unpaved road leading to the area along the edge of Runway 17-35. The disturbed area encompasses most of the peninsula-like feature; however, the open undisturbed area still exists between the runway and the site. The area appears to be unchanged in a

1957 photograph other than the presence of vegetation in the center of the area. Waste activities were not visible at the time (EPA, 1996). The area appears to be slightly more vegetated in a 1959 photograph (USACE, 2000), and an additional road appears to be present leading from the end of the runway to the disturbed area (EPA, 1996). What appears to be a "deep excavation" running east to west in the center of the site was present in 1961 (USACE, 2000). The area appears to be unchanged in 1963 (USACE, 2000) and inactive and revegetated in 1967 (USEPA, 1996). Additional aerial photographic coverage from 1974, 1980, 1982, 1988, and 1994 indicate that the area was inactive and revegetated (USACE, 2000; USEPA, 1996).

3.2 WOD ENVIRONMENTAL INVESTIGATION HISTORY

Environmental actions began at the WOD in August 1986 when the Commonwealth of Virginia conducted an inspection of the site and identified the presence of waste (reported as waste oils) on the surface of the site. Following further inspection and consultation, NASA conducted a removal action in the area from November 12 to December 30, 1986 including the excavation and removal of approximately 180 cubic yards of impacted soils in four separate areas of the site (Figure 3-2). No samples were collected for analysis during or after the excavations. The Commonwealth of Virginia provided NASA with a letter indicating that no further investigations were necessary regarding the potential release of petroleum products at the site (Versar, Inc., 2001a).

A PA consisting of interviews, review of historical records, and a site walk-over was conducted at the WOD in 1988. The PA recommended further investigation and sampling based on the potential for residual contamination and the reported disposal of solvents in the area (Ebasco Services, Inc., 1988). An SI conducted from 1989 through 1992 included the performance of soil gas surveys, surface and subsurface soil and sediment sampling, and the installation and sampling of groundwater monitoring wells.

Two separate soil gas surveys were conducted at the WOD. In August/September 1989, a limited soil gas survey consisting of nine sampling points spaced at 100-foot intervals was conducted. Samples were analyzed using a field instrument. One of the soil gas sample results indicated the presence of elevated concentrations of volatile organic compounds (VOCs) (Ebasco Services, Inc., 1990b). A second soil gas survey, consisting of 37 sampling points, was conducted in June 1990. Sampling points were located throughout and between the areas excavated in 1988, and the samples were analyzed using a field instrument. The results indicated a potential for minor VOC contamination in the area, and further soil and groundwater sampling was recommended (Ebasco Services, Inc., 1990b).

Additional sampling activities were conducted in 1990 and 1992. In 1990, two surface and one subsurface soil, two sediment, and two groundwater samples were collected from the WOD and analyzed for target compound list (TCL), VOCs, semi-volatile organic compounds (SVOCs), pesticides, PCBs, and target analyte list (TAL) metals. The analytical results were not validated and sampling locations were not surveyed. Based on the review of these results, the 1990 SI report identified a potential for contamination and the release of contamination from the site. However, the results were reevaluated as part of the SI review process between 1990 and 1992. In 1992, it was concluded in the final revision to the SI report that there was no analytical evidence that waste remained at the WOD. This conclusion was based on a comparison of the 1990 analytical results and the results of samples collected from five additional borings to action levels, background levels, and EPA guidance criteria (Metcalf & Eddy, Inc., 1992). Five samples were collected from the borings at depths varying from 1 to 15 feet below ground surface and analyzed for total petroleum hydrocarbon (TPH). No TPH was detected in any of the samples (Metcalf & Eddy, Inc., 1992). As a result of these findings, a no further action recommendation was made for the WOD. The analytical data and site history for WOD were reviewed during the completion of a base-wide RCRA Facility Assessment (RFA) conducted in 1991 and 1992. The RFA concluded, based on the 1992 SI Report, that the WOD did not require any further investigation.

No additional work was completed at WOD until 1997. In 1997, monitoring well WFF15-GW7 was installed in the WOD area (see Figure 3-3) as a background well for investigations being conducted at Site 15 (located west of WOD). This well was sampled in 1997 and 1998 as part of the Site 15 RI. The analytical results from these samples indicated the presence of solvent and petroleum compounds (Versar, Inc., 2001a). In response to this finding, NASA conducted an inspection of the WOD and identified an area of stained soil and stressed vegetation (see Figure 3-3). The stained soil area is west of the area that was excavated in 1986, and the ground surface is stained with and contains what appears to be weathered petroleum-based materials.

An RI was conducted at the WOD from 1998 through 2000 and included a review of historical data, the performance of a geophysical survey, the installation and sampling of temporary monitoring wells, sampling of surface and subsurface soils, and the installation and sampling of permanent monitoring wells (Versar, Inc., 2001a). The geophysical survey consisted of an electromagnetic survey using an EM-31 ground conductivity meter conducted to identify the presence of buried metal and nonmetal objects. The survey was conducted over a 200,000-square-foot area extending from the runway to about 190 feet north of monitoring well WFF15-GW7 and about 150 feet west to about 350 feet east of WFF15-GW7. The survey indicated that the WOD did not contain large areas of buried material or a large burial area. Two small areas of possible buried metal debris were identified. The survey findings were confirmed through the advancement of soil borings throughout the area (Versar, Inc., 2001a).

The geophysical survey was followed by the advancement of 31 soil borings using direct push methodology throughout the stained soil area and the area covered by the geophysical survey. The borings were extended into the water table and ranged in depth from 12 to 30 feet below ground surface. Twenty-seven of these borings were converted to temporary monitoring wells and were sampled and analyzed for VOCs and TPH [gasoline range organics (GRO) and diesel range organics (DRO)] using an on-site mobile laboratory and for arsenic using an off-site laboratory. The analytical data were not validated but were used to select locations for permanent monitoring wells (Versar, Inc., 2001a). The temporary wells were surveyed, and water level data were recorded for each well.

Based on the data collected from the temporary wells, six new permanent monitoring wells were installed in the study area (WFF16-GW1, WFF16-GW-2S, WFF16-GW2D and WFF16-GW3 through WFF16-GW5, see Figure 3-4). Groundwater samples were collected from these wells and existing wells MW-3, WFF15-GW1 and WFF15-GW7 on four occasions from 1997 through 2000. Samples were collected in April 1997 and March 1998 from WFF15-GW1, WFF15-GW7 and MW3 as part of the Site 15 RI. Samples were collected from monitoring wells WFF16-GW1 through WFF16-GW5 in May 1998. The final round of sampling was conducted in February 2000 and included samples from the new monitoring wells and WFF15-GW7. All samples were collected using hand bailers and analyzed for TCL organics, TAL inorganics, and TPH (GRO and DRO), and the analytical results were validated using EPA validation protocol (Versar Inc., 2001a). All monitoring wells were surveyed, and water level measurements were taken during each round of sampling. In addition to groundwater sampling, other groundwater investigations included a groundwater tidal influence study conducted at monitoring well WFF15-GW7 and slug testing conducted at nearby wells installed during the Site 14 and 15 RI. These aquifer tests were conducted as part of the Site 14 and 15 RI concurrent with the WOD RI (Versar, Inc., 2001b).

Soil investigations conducted during the WOD RI included the collection of 21 surface soil and 4 subsurface soil samples collected from within and immediately around the area of stained soil and stressed vegetation (Figure 3-4). Samples were analyzed for TCL organics, TAL inorganics, and TPH (GRO and DRO), and the analytical results were validated using EPA validation protocols. Surface soil samples were collected from 0 to 6 inches below ground surface, and subsurface samples were collected at varying depths ranging from 17 to 24 feet below ground surface (Versar, Inc., 2001a). Based on the findings and results of the investigation, an RI/FS report for the WOD was prepared in March 2001 (Versar, Inc., 2001a). The RI findings are presented in more detail in the Supplemental RI work plan (TtNUS, 2003a) and discussed in Sections 3.4 and 5.0 of this report.

3.3 WOD ENVIRONMENTAL SETTING

3.3.1 Topography and Surface Water

The WOD is currently an open field vegetated with grasses, shrubs, and bushes. The southern half of the site is relatively flat with little slope, and is grass covered. The central portion of the site slopes to the north and east, with a change in elevation from about 28 feet above msl to about 12 feet msl over a 1,200-foot distance. The northern, eastern, and western boundaries of the site are formed by steep slopes that direct non-infiltrated surface runoff into low-lying marshes that border an unnamed tributary to Little Mosquito Creek and Little Mosquito Creek. There are no surface water bodies within or immediately adjacent to the disposal areas at the WOD. The closest body of water is a narrow, unnamed tributary to Little Mosquito Creek located about 160 feet west of the site. Approximately 300 feet of marshland to the north and east separate WOD from Little Mosquito Creek.

3.3.2 WOD Soils

The WOD Site is located near the northern perimeter of the MB, north of the end of Runway 17-35. The soils at the WOD belong to the Molena series (see Figure 2-3) (USDA, 1994). These soils are described as a well-drained, fine to coarse sandy loam with low organic content. Because the WOD is adjacent to a main runway and considering the past operations at the site, it is likely that the soils at the WOD have been disturbed and reworked. Considering the natural topography of the area, it is possible that the WOD experienced some filling with soil materials from nearby portions of the MB that consist of Bojac series soils. These soils are of similar type but are reported to have a higher percentage of finer-grained sands.

3.3.3 WOD Geology as Determined by Previous Investigations

The boring logs generated during the RI (Versar, Inc., 2001a) indicated that the geology of the Columbia Group beneath WOD is generally similar to the regional geology. The geologic materials were reported to consist of a fine-to medium-grained quartz sand with some silt, and the lithology did not differ significantly throughout the site.

A sandy clay layer was consistently encountered at depths ranging from 10 to 27 feet below ground surface, or (considering the differences in site topography) at an elevation near sea level, and was also encountered in adjacent Site 15 near the same elevation. The thickness of this clay at the WOD was reported to be as much as 5 feet. Based on the local and regional stratigraphy, this clay was not believed to represent the upper Yorktown aquitard, which at the nearby Fire Training Area was encountered at an elevation of about

25 feet below sea level (Metcalf & Eddy, Inc., 1996b). It was concluded that the clay layer was a localized lens within the Columbia Group. Laterally extensive, fine-grained deposits would not be unusual for the paleoenvironmental and depositional conditions of the Columbia Group (i.e., probable channel and overbank sediments deposited in a low-relief, coastal plain setting) that existed during the Pleistocene Era.

3.3.4 Groundwater as Determined by Previous Investigations

Groundwater occurrence and flow characteristics for WOD have been interpreted and reported in the RI/FS for the WOD (Versar, Inc., 2001a) and for adjacent Site 15 in the RI/FS for Sites 14 and 15 (Versar, Inc., 2001b). These studies only investigated the Columbia Group; no monitoring wells were installed into the Yorktown Formation.

The depth to groundwater beneath the WOD is variable due to the varying topography across the site. In March 2000, the depth to groundwater varied from about 23 feet at monitoring well WFF16-GW-1 (located near the end of the runway) to about 6 feet at well WFF16-GW-5 (located along the northwestern border of the site and adjacent to Site 15) (see Figure 3-4). In May 1998, the static water elevations were generally about 0.5 foot higher than in March 2000. Groundwater elevations in the Site 15 monitoring wells are also pertinent to this investigation because they monitor the groundwater conditions near the suspected groundwater discharge point at the unnamed tributary to Little Mosquito Creek. Depths to groundwater in the Site 15 monitoring wells were not measured during either round of the WOD RI but have historically been very shallow, consistent with their position adjacent to (or within) a groundwater discharge zone. Because the groundwater elevation data for WOD are limited, no conclusions can be reached regarding the degree of seasonal fluctuation nor the effects of varying weather cycles (wet versus drought) on the position of the water table at this site.

Contour mapping of the water table and an interpretation of groundwater flow direction were presented in the RI (Versar, Inc., 2001a). This interpretation indicated that the general direction of groundwater flow at and near the water table was consistent with and generally mimicked the surface topography, which is common for shallow, unconfined aquifers. Figure 3-5 presents the groundwater contour interpretation from the RI and indicates that the WOD is basically bisected by a groundwater divide that trends north-to-northeastward through the peninsula, although the hydrogeological interpretations concerning the presence and position of the divide (and all interpretations east of the divide) are severely constrained by a lack of groundwater data from the eastern half of the peninsula (Versar, Inc., 2001a). Groundwater to the west of the divide is indicated as flowing in a generally west to northwestward direction and toward the unnamed tributary to Little Mosquito Creek. Based on this interpretation, it was assumed that the groundwater flowing from the western side of the WOD discharges into the unnamed tributary to Little Mosquito Creek that flows through Site 15 and the wetlands adjacent to Little Mosquito Creek. Groundwater east of the divide was

assumed to flow in a generally east to northeastward direction and flow toward and discharge into Little Mosquito Creek and its adjacent wetlands.

3.4 CONCEPTUAL SITE MODEL (CSM)

As described in Section 3.2, a series of environmental investigations and actions occurred at the WOD from 1986 through 2000. The following sections present an overview of the nature and extent of contamination identified in these investigations and discusses the analytical results and physical characteristics of the WOD in the form of a general CSM. Many of the earlier investigations did not include the rigorous analytical data handling and validation requirements that are necessary to support the completion of a CERCLA RI or risk assessment. However, that analytical data is referred to for collaborative or comparison purposes where appropriate.

3.4.1 Surface Water and Sediment

There are no surface water bodies within the WOD nor are there any surface water bodies located immediately adjacent to the disposal sites. The majority of the WOD is relatively flat, and the majority of precipitation is expected to infiltrate into the ground. The perimeter of the WOD is sloped such that overland flow from the site enters low-lying, poorly drained areas or marshes that border nearby surface water bodies. The closest stream is an unnamed tributary to Little Mosquito Creek located about 160 feet to the west of the WOD. The headwaters of this unnamed tributary are formed by a permitted outfall that discharges water from the stormwater management system, wash racks and oil/water separator located at the main airfield hangar. Additionally, the tributary flows adjacent to and between FUDS Sites 9, 14 and 15. Little Mosquito Creek is located about 300 feet north of the WOD. The unnamed tributary, Little Mosquito Creek, and other nearby surface water bodies in the area have been sampled and evaluated as part of RI/FS activities at Sites 14 and 15. These investigations included the collection and analysis of surface water, sediment, and ecological receptor (target) tissue samples (Versar, Inc., 2001b). Because there is no direct surface flow between the WOD and these surface water bodies, no surface water samples have been collected in conjunction with WOD investigations.

3.4.2 Soils

Twenty-one surface soil samples were collected from WOD during the 2000 RI. All of these samples were collected in and around the area of stained soil and stressed vegetation (Figure 3-4). No other areas within WOD were sampled during the RI. However, prior to collecting surface soil samples, a visual inspection and geophysical survey were conducted throughout the study area. No other areas of waste disposal were evident or identified as a result of these surveys (Versar, Inc., 2001a). Based on this

observation, the surface soil sampling program focused on the area that exhibited visual evidence of contamination.

The 21 surface soil samples were analyzed for VOCs, SVOCs, pesticides/PCBs, and TAL inorganics, and the analytical results were validated using EPA-approved methods and protocols (Versar Inc., 2001a). Eight organic compounds and 20 metals were positively identified in the WOD surface soil samples. Positive results for DRO and GRO TPH were also identified in these samples. Of the eight organic compounds detected, five were SVOCs and the remaining three were pesticides. The full analytical results for these surface soil samples are discussed in Section 5.0 of this report.

Benzo(a)pyrene was identified as the major surface soil contaminant of concern at the WOD. It was detected in two samples at concentrations greater than human health risk-based screening concentrations. Samples 3WFF16-SS9 and 3WFF16-SS10 (see Figure 3-4) contained benzo(a)pyrene at 910 ug/kg and 1,200 ug/kg, respectively (Versar, Inc., 2001a). Both of these samples were collected from the center of the stained soil area.

Metals analytical results were fairly consistent across the site and were similar to background levels. Pesticide analytical results consisted of isolated, low-level detections that did not indicate an association with site activities.

An ecological risk assessment (ERA), conducted in accordance with EPA guidance, was completed as part of the WOD RI (Versar, Inc., 2001a). An ecological characterization including a review and identification of habitat types, organisms, populations, communities, and endangered species occurrence associated with the WOD was conducted. Surface soil sample results were compared to EPA Region 3 biological technical assistance group (BTAG) screening levels to identify contaminants of potential concern (COPCs) for the ERA. Thirteen contaminants were identified as COPCs based on this screening. Based on the habitat characterization and potential exposure routes, risk assessment endpoints including terrestrial plants, soil invertebrates, small carnivorous mammals, and small carnivorous birds were selected for evaluation. Toxicity data and exposure pathway parameters, using EPA guidelines and published reference data, were evaluated for each COPC and risk assessment endpoint to characterize potential WOD ecological risks. Based on this assessment, the RI concluded that there was a very limited potential for adverse ecological impacts from several metals present in WOD surface soils (aluminum, chromium, lead, vanadium, and zinc). The metals that contributed most to the potential adverse impacts were aluminum and chromium. The WOD concentrations of these metals were noted as being at or less than background concentrations (Versar, Inc., 2001a).

Four subsurface soil samples, one from each boring (see Figure 3-4), were collected during the RI and analyzed for the same parameters as surface soils. The analytical results were validated as described above and discussed in full in Section 5.0 of this report.

The analytical results for the subsurface soil samples indicated the elevated presence of VOCs and SVOCs. Ethylbenzene was detected at concentrations ranging from 1,100 ug/kg to 2,200 ug/kg. Toluene and xylene concentrations as high as 1,700 ug/kg and 13,000 ug/kg respectively, were detected. The highest concentrations of these VOCs were detected in the sample collected from boring SB-2 (2WFF16-SB2). This boring, located near the eastern border of the stained soil area, also contained the most significant number and concentrations of SVOCs (2-methylnapthalene at 29,000 ug/kg; naphthalene at 7,700; phenanthrene at 7,800 ug/kg). Similar but slightly lower concentrations of these contaminants were identified in the sample collected from boring SB1 (2WFF16-SB1). Only trace or estimated low levels were detected in samples collected from SB3 and SB4. Benzene was not reported as detected in any of the surface or subsurface soil samples (Versar, Inc., 2001a).

Metals were detected in the subsurface soils but at levels that appeared to be consistent with surface soil levels identified at the site and in background samples collected from the area (Versar, Inc., 2001a).

3.4.3 Groundwater

Nine monitoring wells at WOD were sampled as part of the RI. The sampling occurred on four occasions from April 1997 through February 2000. No single round of sampling included all nine wells. Groundwater samples were analyzed for VOCs, SVOCs, and TAL inorganics. The analytical results were validated using EPA validation protocols (Versar, Inc., 2001a). Data from the four sampling events were pooled into one database and used for evaluating site characteristics presented in the RI (Versar, Inc., 2001a).

Analytical results from the four sampling rounds indicated significant detections of VOCs, SVOCs, and metals. The analytical results were evaluated in the 2001 RI to identify the significance and nature and extent of the groundwater contamination. This evaluation included the comparison of groundwater contaminant levels to EPA Region 3 tap water risk-based screening concentration (RBCs) and Maximum Contaminant Levels (MCLs) and examining the occurrence and distribution of the detected contaminants. As a result of this evaluation, benzene, toluene, 1,2-dichloroethene (1,2-DCE), ethylbenzene, several SVOCs, arsenic and lead were identified as the major contaminants that characterized the extent and significance of contamination at the site.

With one exception, the maximum concentrations of organic and metals contamination were detected in monitoring well WFF15-GW7 (see Figure 3-4). The only exception was 1,2-DCE for which the maximum concentration (8 ug/L) was detected in well cluster WFF16-GW2S/D. Monitoring wells WFF15-GW7 and WFF16-GW2S/D are located at opposite ends of the stained soil area. These two wells also contained significant concentrations of benzene (maximum 58 ug/L), toluene (maximum 1,400 ug/L) and ethylbenzene (maximum 280 ug/L). Benzene, toluene, 1,2-DCE, and ethylbenzene were either not detected or detected at infrequent low levels (below RBCs) in other wells (Versar, Inc., 2001a).

SVOCs detected at significant levels included 2-chlorophenol, 2-methylnaphthalene, 4-methylphenol, carbazole, dibenzofuran, naphthalene, and phenanthrene. All of these SVOCs were detected almost exclusively at WFF15-GW7, WFF16-GW2S, and WFF-16-GW2D. The highest and most frequent detections, and the only levels in excess of the tap water RBCs, were at WFF15-GW7. These compounds were either not detected or present at trace estimated concentrations in other wells.

Monitoring well WFF15-GW1, located in the projected downgradient direction from the stained soil, was the only other well that consistently contained a similar contaminant pattern as monitoring wells WFF15-GW7, WFF16-GW2S, and WFF-16-GW2D. However, the frequency and levels of detection in this well were significantly less than in the upgradient wells, and for the most part concentrations did not exceed MCLs or RBCs.

Arsenic and lead were the most significant metals detected during the groundwater sampling events. Similar to the organic contamination pattern, the maximum concentrations (arsenic at 88.2 ug/L and lead 62.8 ug/L) were detected in well WFF15-GW7. Samples collected from wells WFF16-GW2S and WFF-16-GW2D were the only other samples that contained arsenic and lead levels greater than reported background levels.

3.4.4.4 Summary of CSM as Determined By Previous Investigations

Based on historical records and the available analytical and groundwater level results, it was concluded in the RI that past waste oil disposal activities at the WOD were the source of a limited groundwater contamination plume. Groundwater in the area occurs in an unconfined water table aquifer within the Columbia Group that is isolated by an aquitard from the lower Yorktown Formation. A groundwater divide was interpreted to exist at the WOD, and groundwater was projected to flow in a northwesterly and northeasterly direction from the crest of the site. Groundwater measurements and subsequently projected groundwater contours indicated that the groundwater was relatively flat with no steep gradients. The groundwater plume, consisting of organic and metal contaminants, appeared to be fairly stable and located immediately beneath and/or slightly downgradient of the area of stained soils.

This conceptual model of the site is limited by the number and location of samples collected to date. Historical records indicate that the WOD site consists of an area more expansive than that addressed in the RI. Although a removal action was completed in other disposal locations at the WOD, no samples were collected at the time of the removal, and no surface or subsurface investigations have been conducted in those areas since. In addition, a limited number of monitoring wells are available to characterize the groundwater at the site. Surface runoff patterns have not been investigated to date to characterize the potential impact of the site on the surrounding wetlands.

3.5 PLANNED SUPPLEMENTAL REMEDIAL INVESTIGATION

Supplemental RI activities to refine the CSM and meet the objectives identified in Section 1.1 of this report were defined in a final work plan (TtNUS, 2003a). That work plan includes a detailed description of the field effort, data handling and management, and data evaluation process and methodologies to be applied in completing this Supplemental RI. The work plan includes a Sampling and Analysis Plan (SAP) and a Quality Assurance Project Plan (QAPP) that provide a discussion of methods and procedures to be applied in performing the Supplemental RI. The sampling program presented in the work plan is summarized in the following sections. Pesticide analysis was not included in any of the Supplemental RI site-specific samples. This decision was based on a review of existing historical information and analytical data which indicated that pesticides were not associated with any site-specific activity. In addition, because of the lack of an association with any site specific activity or finding, historical pesticide results were not to be included in any supplemental data evaluations.

3.5.1 Background Study

The work plan presents a review of background surface and subsurface soil and groundwater data available from historical investigations conducted at WFF. In addition, the work plan discusses the completion of a separate study to be conducted within the MB to characterize the two major soil types (Bojac and Molena) present within the MB and to collect additional groundwater data. The completion of the MB background study includes the evaluation of existing data and the compilation of historical and new data for application under this Supplemental RI. No background soil samples were planned as part of the Supplemental RI program. Site-specific background groundwater samples were to be collected from monitoring well MW-3. The groundwater samples were to be analyzed for VOCs plus Methyl Tri-Butyl Ethane (MTBE), SVOCs, PCBs, TAL total and dissolved metals (field-filtered), and monitored natural attenuation (MNA) parameters [hydrogen, soluble manganese, nitrate, chloride, sulfate, methane/ethane/ethene, and total organic carbon (TOC)]. Groundwater field parameters [pH, temperature, dissolved oxygen, oxidation reduction potential (ORP), salinity, conductivity, turbidity, alkalinity, ferrous iron, and hydrogen sulfide] also were to be measured at each well.

3.5.2 Soils

Soil sampling activities to be conducted to further characterize the WOD were to consist of collecting 25 surface and 25 subsurface samples. The study area was defined as that area north of the end of Runway 17-35 starting at about 160 feet north of the runway and extending throughout the peninsula-like feature. This area was defined through a review of background information and historical aerial photographs that indicated suspected former disposal and/or disturbed zones within this area. The samples were to be collected at locations placed on approximate 80-foot centers to allow for coverage of the entire study area and to investigate the presence or absence of waste materials, residues, or contamination associated with past use of the area for waste disposal. Several specific areas of interest were identified and sampling locations were adjusted from the 80-foot centers to include sampling locations immediately upgradient of monitoring wells WFF15-GW7 and WFF16-GW2 S/D.

A surface soil sample consisting of soils from 0 to 6 inches below ground surface was to be collected from each location. In addition, a boring was to be advanced to the water table at each location to characterize the subsurface materials and allow for the collection of subsurface samples. A subsurface sample was to be collected from each boring at evidence of waste or at the depth of the highest photoionization detector (PID) reading, or at mid-depth if no waste or elevated PID readings were encountered. Samples were to be analyzed for VOCs, SVOCs, PCBs, and TAL metals. Additionally, surface soil samples were to be analyzed for TOC, pH and grain size.

3.5.2.1 Marsh Area Soils

Additional surface soil samples were to be collected around the perimeter of the former disposal area near the marshlands that surround the WOD to characterize any potential releases associated with runoff from the former disposal area. Eleven surface soil samples (0 to 6 inches in depth) were to be collected from depositional areas along the perimeter of the WOD. Sampling locations were to be selected in the field based on field conditions and were to be located at the base of the embankment around the site, in areas of potential erosion and runoff, and spaced to ensure adequate coverage of the marsh soils along the eastern, northern, and western sides of the site. Samples were to be analyzed for VOCs, SVOCs, PCBs, TAL metals, TOC, pH, and grain size.

3.5.3 Surface Water

Surface water was not expected to exist in the immediate vicinity of the WOD. The work plan indicated that if open surface water channels that potentially receive runoff from the site were noted during the selection of marsh soil sampling locations, the surface waters and sediments would be sampled. In

addition, if leachate outbreaks or seeps were noted, these were also to be sampled. If surface water samples were required, they were to be analyzed for VOCs, SVOCs, PCBs, and TAL metals. Sediment samples, if collected, were to be substituted for the marsh soil samples and analyzed for the same parameters. In addition, a separate surface water sample was to be collected and analyzed for TAL dissolved metals analysis.

3.5.4 Groundwater

The groundwater investigation was to consist of the installation of new monitoring wells, the redevelopment of existing wells, the collection of groundwater samples, and two rounds of synoptic groundwater level measurements. Three new wells (including a replacement well for MW3, which was noted to be damaged) were to be installed at the WOD to allow for better characterization of groundwater flow patterns and to provide sampling points to characterize groundwater conditions in the eastern and northern portions of the site. The well screens were to be installed across the water table.

All monitoring wells (new and existing) were to be developed prior to the performance of groundwater level measurement and sampling activities. Sampling was to occur no sooner than 10 days after completion of well installation and development. Samples were to be collected using low-flow methods and analyzed for VOCs, SVOCs, PCBs, TAL total and TAL dissolved metals (field-filtered), and MNA parameters (hydrogen, soluble manganese, nitrate, chloride, sulfate, methane/ethane/ethene, and TOC). In addition, groundwater field parameters [dissolved oxygen (DO), ph, ORP, salinity, conductivity, turbidity, temperature, alkalinity, ferrous iron, and hydrogen sulfide] were to be measured at each well.

4.0 SUPPLEMENTAL RI INVESTIGATIONS

4.1 BACKGROUND STUDY

A background study of soils and groundwater for the WFF MB area was conducted in 2003. The results of that study are presented in a report, Background Soils and Groundwater Report for the Main Base at National Aeronautics and Space Administration (NASA) Wallops Flight Facility (WFF), dated May 2004 (TtNUS, 2004). The background study included the evaluation of existing background samples as well as the collection and analysis of additional soil and groundwater samples from locations identified as being outside of the influence of known or suspected waste sites or sources of contamination. A separate work plan for the background study, identifying the location of sampling points, analytical protocols, data management, and data evaluation methodologies was approved by the EPA and VADEQ.

The background study included a comparison and statistical evaluation of the similarities and differences among chemical/analyte concentrations detected in the two major soil series (Bojac and Molena) present at the MB. In addition, the study evaluated the similarities and differences between chemical/analyte concentrations detected in surface and subsurface samples within the same soil series. The background study concluded that there are sufficient differences in metals concentrations between Bojac and Molena series soils to consider them dissimilar for background data comparisons. In addition, the study concluded, based on the occurrence and distribution of concentrations of a number of metals, that the surface and subsurface profiles for each soil series were dissimilar and suggested that a compositional difference exists with depth (TtNUS, 2004). For organics, the study concluded that surface and subsurface soils were dissimilar but that no significant differences were apparent between the two soil series. The background study presents the evaluation of the background soils in detail and includes tables of analytical results for each soil series and depth (surface and subsurface).

The soils at the WOD have been categorized as belonging to the Molena series. As indicated above, an evaluation of surface and subsurface background samples within the Molena series indicates that surface and subsurface soils should be evaluated separately. For the purposes of this Supplemental RI, the background data set established in the referenced background report (TtNUS, 2004) will be used to evaluate site-specific soil samples collected and analyzed from the WOD. Tables 4.1 through 4.4 present the occurrence and distribution of substances detected in background surface and subsurface soil samples. Figures 4-1 and 4-2 show the background soil sample locations.

As indicated above, the background study included the evaluation, collection, and analysis of background groundwater samples. The well identified as a WOD site-specific well, MW-3, was sampled during the background study and during the Supplemental RI. The analytical results for both sampling events are shown in Appendix A. Table 4.5 presents the occurrence and distribution of substances in all background

groundwater samples, and Table 4.6 presents the metals results for filtered background groundwater samples. Figure 4-2 shows the location of the MB background monitoring wells.

4.2 SOIL INVESTIGATION AND SAMPLING

Surface and subsurface soil sampling was conducted at the WOD between February 6 and 26, 2003. Sampling locations were surveyed by a licensed professional surveyor, and locations were tied back into benchmarks referenced to the Virginia State Plane Coordinate System, South Zone, North American Datum 1983 (NAD 1983) High Accuracy Recovery Network (HARN) Adjustment, 1993. Elevations were referenced to the National Geodetic Vertical Datum 1929 (NGVD 29). Survey data is presented in Appendix B. Unless indicated below, all work was performed in accordance with the work plan (TtNUS 2003a). The following sections describe any deviations from the work plan, briefly describe the field investigation activities, and present significant observations made during the field investigation.

4.2.1 Surface Soils

The work plan designated 25 surface soil and 11 marsh soil samples for collection and analysis. All samples were to be analyzed for VOCs, SVOCs, PCBs, TAL metals, TOC, pH and grain size.

4.2.1.1 Deviations from the Work Plan

Three additional surface soil samples (WOD-SS-121, -122, and -123) were collected in the area immediately upgradient (south) of the suspected source area near monitoring well WFF15-GW7 (see Figure 4-3). These samples were collected at the location of additional soil borings advanced after encountering elevated PID readings in the subsurface soils at location WOD-SS/SB-102 (see Section 4.2.2 for a discussion of subsurface soil findings). The samples were collected 25 feet west, east, and south of location WOD-SS-102 and were analyzed for VOCs, SVOCs, PCBs, TAL metals, TOC, pH and grain size.

One surface soil sample (WOD-SS-128) collected from the eastern boundary of the WOD (see Figure 4-3), was considered a marsh soil rather than a surface soil because it was collected at the base of a steep embankment, and groundwater was encountered within two feet of the ground surface at this location. The sample was analyzed for VOCs, SVOCs, PCBs, TAL metals, TOC, pH and grain size.

4.2.1.2 Surface Soil Sampling and Analysis

A total of 27 surface soil and 12 marsh soil samples, two more soils and one more marsh soil than anticipated in the work plan, were collected during the Supplemental RI. Figure 4-3 shows the surface and marsh soil sampling locations, along with the 2001 RI sampling locations. All samples were collected and analyzed in accordance with the work plan. Surface soils consisted, in general, of silty fine-to medium-grained sand with some occurrence of clays. The soils around the perimeter of the WOD contained more noticeable amounts of fine silt and less sand. The marsh soil samples, in general, consisted of dark, organic-rich sandy silt. No other significant observations were noted during the investigation. Sample logs for the surface soil and marsh soil samples are presented in Appendix C.

4.2.2 Subsurface Soils

The work plan designated 25 borings and subsurface soil samples for collection and analysis. All samples were to be analyzed for VOCs, SVOCs, PCBs, and TAL metals.

4.2.2.1 Deviations from the Work Plan

Three additional borings (WOD-SB-121, -122, and -123) were advanced in the southern (upgradient) portion of the site, (see Figure 4-4). These borings were located 25 feet west, east, and south of boring WOD-SB102 in response to encountering elevated PID readings in WOD-SB102, which was placed within a suspected source area. Subsurface soil samples were collected from each of these soil borings at the 10 to 12 foot depth interval and were analyzed for VOCs, SVOCs, PCBs, and TAL metals.

One boring at the eastern perimeter of the site was not advanced as planned. The work plan designated that a boring was to be located about 80 feet east of boring location WOD-SB125. During the field investigation, this location was found to be at the base of the embankment, inaccessible to drilling equipment, and located between two marsh soil sampling locations. In addition, the water table in this area was encountered within 2 feet of the ground surface. Because of the location, the elevated water table, and the close proximity of other borings (WOD-SB125 and -SB127), only a surface soil sample was collected from this location.

According to the work plan, borings were to be advanced using direct push technology, and subsurface materials were to be collected in an acetate-lined macrocore sampling device. This technology was not used at soil boring locations WOD-SB126 and -SB127, because the area was not accessible to a direct push rig. These two borings were advanced using an all-terrain vehicle (ATV) drilling rig and split spoons.

Split spoon samples were collected continuously from the surface in these two locations, and the split spoon content was logged and sampled.

Soil recovery was poor at boring locations WOD-SB110 and -SB111. Because the material recovered in the macrocore samplers at these two locations was inadequate for the required sample volume, an additional macrocore was collected at each of these locations. The second boring was driven within several feet of the original location, and the material was sampled to complete the sample volume requirements.

4.2.2.2 Subsurface Soil Sampling and Analysis

A total of 27 subsurface soil samples were collected and analyzed for VOCs, SVOCs, PCBs, and TAL metals as designated in the work plan. The samples were collected from 27 borings that were advanced from ground surface to the water table and were collected at the depth exhibiting the highest PID reading or at mid-depth if no elevated PID readings were encountered, with the exception of sample WOD-SU-117-0102. This sample was collected at the 1 to 2 foot depth because the water table was encountered at 2 feet below the ground surface. Figure 4-5 shows the locations of the subsurface soil samples, along with the 2001 RI subsurface soil sampling locations.

Borings, with the exceptions noted above, were advanced using the direct push method, and the subsurface materials were retrieved using a macrocore sampler, with the recovered material collected in an acetate sleeve. A 2-inch diameter macrocore sampler was used to allow for sufficient volume to log the subsurface lithologies and for the collection of analytical samples. In general, the subsurface material consisted of silty fine-to medium-grained sand with the sand content and grain size increasing with depth. The presence of clay mixed with the sand was also noted in the deeper borings, and the clay content increased with depth. The water table was encountered at a depth of about 23 feet in areas of higher elevation south of the site (WOD-SB102, -SB123 area), 14 to 12 feet below ground surface over the relatively flat portions of the site (from WOD-SB106 to WOD-SB119), and decreased with surface topography to the north (10 to 8 feet at WOD-SB114 and WOD-SB-116). In the areas of lower elevation at or near the base of the embankment that forms the perimeter of the site, the water table was encountered at depths of 4 to 2 feet below ground surface.

Elevated PID readings ranging from 63 parts per million (ppm, benzene equivalent) to 206 ppm and a strong fuel odor were recorded in soil boring WOD-SB102. These were encountered from the 15 foot depth down to total depth of 24 feet below ground surface. The highest PID reading (206 ppm) was recorded at the water table, which was approximately 21.5 feet below the ground surface. Because of these observations and because this boring was located immediately upgradient of monitoring well

WFF15-GW7, which historically contained the most significant contamination, three additional borings (WOD-SB-121, -122, and -123) were advanced 25 feet to the west, east and south. No evidence of waste materials, odors, or elevated PID readings were noted in these borings until the water table was reached at an approximate depth of 23 feet. Elevated PID readings ranging from 75 ppm to 200 ppm, and a petroleum odor were recorded from soils retrieved from immediately below the water table. No odors or PID readings were noted in the soils above the water table in these borings.

No elevated PID readings were encountered in any of the other borings. However, a layer of soft, wet fill material containing glass, metal, and ceramic fragments and wood and charcoal debris was encountered in borings WOD-SB110 and -SB111. The material was mixed with the silty sand and extended from a depth of 2 to 12 feet and 4 to 10 feet, respectively in these borings. As indicated in Section 4.2.2.1, two borings were advanced in both of these locations because of poor soil recovery in the first macrocore sampler. The same subsurface material was encountered in the second set of borings, and a sandy clay was encountered at the 12 foot depth immediately below the fill material. Samples were collected from the 2 to 4 foot depth from boring WOD-SB110 and from the 5 to 7 foot depth in boring WOD-SB111. Sample logs and boring logs for the Supplemental RI field program are presented in Appendices C and D, respectively.

4.3 SURFACE WATER

No surface water channels, seeps, or open water was found at the perimeter of the WOD during the Supplemental RI field investigation. No surface water or sediment samples were collected and in accordance with the work plan, the low-lying marsh soil surrounding the WOD was sampled to assess the potential for contaminant migration.

4.4 HYDROGEOLOGIC INVESTIGATION

According to the work plan, two new wells and a replacement background well were to be installed at the WOD and the new and existing (10) wells were to be developed and sampled. Samples were to be collected using low-flow methods and analyzed for VOCs, SVOCs, PCBs, TAL total and dissolved metals (field-filtered), and MNA parameters (hydrogen, soluble manganese, nitrate, chloride, sulfate, methane/ethane/ethene, and TOC). In addition, groundwater field parameters (DO, pH, ORP, salinity, conductivity, turbidity, temperature, alkalinity, ferrous iron, and hydrogen sulfide) were to be measured at each well.

Hydrogeologic investigations were conducted at the WOD between February 10, and March 18, 2003. The following sections describe any deviations from the work plan, briefly describe the field investigation, and

present significant observations made during the field activities. Unless noted below, all samples were collected and analyzed in accordance with the final work plan (TtNUS, Inc., 2003a). Figure 4-6 shows the locations of the newly installed and existing wells at the WOD. All new and existing wells were surveyed by a licensed professional surveyor and locations were tied back into benchmarks referenced to the Virginia State Plane Coordinate System, South Zone, North American Datum 1983 (NAD 1983) High Accuracy Recovery Network (HARN) Adjustment, 1993. Elevations were referenced to the National Geodetic Vertical Datum 1929 (NGVD 29). Survey data are presented in Appendix B.

4.4.1 Monitoring Well Installation and Development

The work plan called for the installation of one replacement and two new monitoring wells to be constructed with 10-foot screened intervals placed across the water table. Rationale for well placement is contained in the work plan and Section 3.5.4 of this report.

4.4.1.1 Deviations From the Work Plan

Because of the shallow water table encountered during the installation of the two new wells (WFF16-GW6 and -GW7), these wells were constructed using a 5-foot screen rather than the planned 10-foot screen. A shorter screen was used to ensure that the water table intersected the screened interval and the wells met the objectives defined in the work plan (TtNUS, 2003a). Well construction was also modified to accommodate the shallow nature of these wells. The filter pack was placed to extend 1 foot above the screen rather than the planned 2 feet, and a 1.5 feet thick bentonite seal was placed above the filter pack rather than the planned 2 feet thick seal.

Several deviations from the well development procedures described in the work plan were necessary because of low water levels and yields. These deviations consisted of the following:

- Due to low water levels and yields, monitoring wells WFF16-GW2S, WFF16-GW4, WFF16-GW5 and WFF15-GW2 were developed using peristaltic pumps and/or hand bailers instead of submersible pumps.

- Monitoring well WFF16-GW1 was not developed because there was only 1 foot of water in the well, which was an insufficient volume to operate a submersible or peristaltic pump or allow for bailing.

- Monitoring well WFF16-GW3 was not developed because the well was dry during the well development phase of the investigation.

4.4.1.2 Monitoring Well Drilling, Construction, and Development

One replacement well and two new monitoring wells were drilled, constructed, and developed at the WOD. Existing monitoring well MW-3 was abandoned by removing the surface/security casing and the well casing to a depth of 1 foot below the ground surface and filling the well casing, by tremie pipe, with a cement/bentonite grout mixture. The surface pad was removed and the top 1 foot of the well boring and the surface area around the abandoned well were filled with cement. The replacement well, WFF15-MW3R, was installed as the WOD site-specific background well (see Figure 4-6). Monitoring wells WFF16-GW6 and -GW7 were installed along the eastern edge of the WOD to provide monitoring points for groundwater sampling and water level measurements in areas where no data points existed.

The wells were installed using the hollow-stem auger drilling method. Continuous split-spoon samples were obtained and lithologically logged for WFF15-MW3R (see Appendix E). Monitoring wells WFF16-GW6 and -GW7 were installed in soil borings WOD-SB124 and -127, respectively, so no separate drilling logs were prepared for these borings. The wells were constructed with 2-inch diameter PVC well screens and risers. The well screen openings were 0.010 inch wide (10-slot). The filter pack consisted of appropriately sized sand (Morie No. 1 or equivalent) and extended from the bottom of the borehole to a height of approximately 2 feet above the top of the screen, except as noted above. The filter pack was emplaced by pouring the sand into the borehole and around the screen. An annular seal consisting of bentonite chips or pellets was installed above the filter pack. The seal had a minimum thickness of 2 feet, except as noted above, and was allowed to fully hydrate per the manufacturer's recommendations before the remainder of the borehole was backfilled. The remainder of the annular space was backfilled with a bentonite/cement grout (approximately 5 pounds of bentonite and 7 gallons of potable water per 94-pound bag of Portland cement). A concrete collar was installed from a depth of 2 feet to the ground surface and around the steel protective standpipe. Well construction diagrams for these wells are contained in Appendix E.

Existing monitoring wells were re-developed and all new monitoring wells were developed. Wells were developed with a submersible pump except where low yields required the use of peristaltic pumps and hand bailers. A surge block was used as an aid in well development. Turbidity was monitored during development, and well development continued until a turbidity value of less than 10 NTU was achieved, or for a maximum of 3 hours. The field geologist recorded the field-measured parameters of pH, conductivity, dissolved oxygen, and turbidity on well development logs. Groundwater elevations were obtained prior to and after well development activities. All groundwater generated during well development activities was containerized for subsequent characterization and appropriate disposal.

Significant observations recorded during well development are presented below:

- A 0.4-feet thick petroleum product layer was present on the surface of the water column in WFF15-GW7 before well development. During development, the water was noted to have sheen, and a product layer developed after containerization. At the completion of well development activities, no measurable product layer was present in the well.

- A petroleum odor was noted during the development of WFF16-GW2S. There was no noticeable sheen in the development water after containerization. No petroleum odor was noted when samples were obtained from this well about 2 weeks later.

- Sulfur-like odors and very low yields were encountered during the development of monitoring wells WFF16-GW4 and -GW5. No odors were noted in these wells during subsequent sampling activities.

- Similar sulfur-like odors were noted at WFF15-GW1 and -GW2 during both development and sampling activities.

4.4.2 Water Level Measurements

Two rounds of synoptic water level measurements were conducted. The first round, prior to monitoring well sampling, was performed on March 3, 2003 after a significant snowfall/melt event. The second round of water level measurements was performed on March 19, 2003, several days after the conclusion of monitoring well sampling. Water level measurements, well construction, and elevation data are presented in Table 4-7.

4.4.3 Groundwater Sampling and Analysis

As indicated above and in the work plan, a complete round of groundwater samples was to be collected from 13 monitoring wells at the WOD. Samples were to be collected using submersible bladder pumps, or peristaltic pumps if necessary, and in accordance with EPA Region 3 low-flow (low-stress) sampling guidelines. Samples were to be analyzed for VOCs, SVOCs, PCBs, TAL total and dissolved metals (field-filtered), and MNA parameters (hydrogen, soluble manganese, nitrate, chloride, sulfate, methane/ethane/ethene, and TOC). In addition, groundwater field parameters (DO, pH, ORP, salinity, conductivity, turbidity, temperature, alkalinity, ferrous iron, and hydrogen sulfide) were to be measured at each well.

4.4.2.1 Deviations From the Work Plan

Several slight deviations in the sampling occurred due to well yields and volume. Deviations from the plan include:

- Monitoring wells WFF16-GW1 and -GW2S went dry during sample collection. Sufficient sample volume was obtained using the standard low-flow sampling technique for all parameters except hydrogen. The hydrogen sample was collected the following day after the well was allowed to recharge.

- Monitoring well WFF16-GW5 exhibited a very low yield during the low-flow sample purging phase, and the well was pumped dry before samples could be collected. The well was allowed to recharge overnight before sampling. The well yield was insufficient to support the collection of hydrogen samples from the well. All other samples were collected according to the work plan.

- Sampling at monitoring well WFF16-GW3 was conducted using a peristaltic pump. The water level in this well was too low to allow for operation of the submersible bladder pump. The sampling was conducted in accordance with the SAP and EPA Region 3 "Low-Flow" (Low-stress) sampling guidelines, and the "straw" method was used to collect the VOC samples.

4.4.3.2 Groundwater Sampling

A total of 13 monitoring wells (3 newly installed and 10 existing wells) were sampled during the Supplemental RI from March 12 through March 18, 2003. Samples were obtained using low-flow sampling techniques with a few minor exceptions noted above. All samples were analyzed for the parameters noted above with the exception of monitoring well WFF16-GW5. The yield was too low in this well to sustain sufficient water flow to allow for the collection of a hydrogen gas sample. Figure 4-7 shows the locations of the 13 wells sampled during the Supplemental RI. Field measurements and MNA parameter data were collected from the wells during the sampling effort and are presented in Table 4.8.

The following observations were noted during the sampling:

- Monitoring wells WFF15-GW7 and WFF16-GW2S were checked for the presence of a petroleum product layer before sampling. A 0.06-feet thick layer of petroleum product was measured in WFF15-GW7. There was no product layer or petroleum odor present at WFF16-GW2S.

- A PID reading of 10.4 ppm was obtained in the wellhead at WFF15-GW7.

- A PID reading of 0.5 ppm was obtained in the wellhead at WFF16-GW2S.

- A PID reading of 0.8 ppm was obtained in the well head at WFF16-GW5.

- Sulfur-like odors but no PID reading was noted during the sampling of monitoring wells WFF15-GW1 and -GW2.

Samples from the following wells had a noticeable color or the well failed to achieve the targeted 5 NTU turbidity reading after purging:

- The sample from WFF15-GW7 was described as "slightly cloudy." Turbidity in this well stabilized at 15 NTUs after 2 hours of purging. The initial turbidity reading in this well was 155 NTUs.

- Turbidity in WFF16-GW2S decreased from an initial reading of 83 NTU and stabilized at 9 NTUs after 2 hours of purging. The sample was described as "clear."

- Turbidity in WFF16-GW2D decreased from an initial reading of 76 NTU and stabilized at 7.5 NTUs after 1.5 hours of purging. The sample was described as "clear."

- The sample from WFF15-GW2 was described as "light brown." Turbidity in this well stabilized at 18 NTUs after 1.75 hours of purging. The initial turbidity reading in this well was 52 NTUs.

- The sample from WFF16-GW5 was described as "light brown." Turbidity readings in this well decreased from 100 NTUs to 48.5 NTU before the well ran dry after 0.5 hours of purging at rates decreasing from 100 ml/minute to 25 ml/minute. The well fully recovered after 0.5 hours and the turbidity was measured at 76 NTUs. The well was purged for another 15 minutes and the turbidity decreased to 27.4 NTUs before the samples were collected.

- The sample from WFF16-GW4 was described as "light brown." Turbidity in this well remained elevated and stable even after 2 hours of purging. Turbidity readings only decreased from 94.9 NTUs to 90.7 NTU after 2 hours of purging.

- The sample from WFF16-GW7 was described as "slightly tan." Turbidity in this well stabilized at 9 NTUs after 1.5 hours of purging. The initial turbidity reading in this well was 188 NTUs.

- The sample from WFF-MW4 was described as "light brown." Turbidity in this well remained high and stabilized at 130 NTUs after 2.5 hours of purging. The initial turbidity reading in this well was 357 NTUs.

4.5 GEOLOGY

The borings completed during the Supplemental RI generally confirm the site geology described in the 2001 RI (Versar, Inc., 2001a). The lithologic unit immediately underlying the site, the Columbia Group, was found to consist of predominantly fine to medium sand with lesser amounts of silt and clay. The lithology was consistent throughout the site.

During the 2001 RI, a sandy clay layer was frequently encountered at an elevation around sea level (Versar, Inc., 2001a). This clay layer was also encountered in the three Supplemental RI well borings and in a majority of the soil borings at the WOD that extended to sea level (see Appendices D and E for boring logs). The clay layer was typically 1 to 2 feet thick and varied in composition from clayey sand to silty clay to clay.

Fill material was encountered in two soil borings, WOD-SB-110 and WOD-SB-111 (see Section 4.2.2.2). The fill consisted of various debris (glass, concrete, wire, ceramic, metal, charred wood) in a silty sand matrix and was encountered at a depth of approximately 4 feet and extended at least to 12 feet in SB-110 and to 10 feet in SB-111.

The thickness of the Columbia Group was not investigated during the 2001 RI or the Supplemental RI. However, during concurrent drilling operations at the nearby FFTA, the Columbia Group was found to be approximately 50 feet thick. The bottom of the Columbia Group was marked by a clay layer, the upper Yorktown aquitard, which was encountered at the FFTA at an elevation of approximately 22 feet below sea level. None of the borings at the WOD were deep enough to encounter this unit.

4.6 HYDROGEOLOGY

Groundwater levels were measured in the WOD area monitoring wells on March 3 and 19, 2003. Table 4-7 provides information regarding the well depths, static water level measurements, and water level elevations. In general, the water levels on March 19 were slightly higher (up to 0.14 meters/0.44 feet) than those measured on March 3. The depth to groundwater at the WOD on March 19 ranged from 7.99 meters (26.20 feet) in WFF15-MW3R, near the end of Runway 17-35, to 0.87 meters (2.95 feet) in WFF15-GW1, on the bank of the unnamed tributary to Little Mosquito Creek (see Figure 4-8).

The groundwater elevation contours for the shallow groundwater at the WOD are illustrated in Figure 4-8. The current interpretation generally agrees with that of the 2001 RI. The groundwater flow directions reflect the influence of surface topography. The site is on a small peninsula that extends from the end of Runway 17-35 towards Little Mosquito Creek to the north. A groundwater divide bisects the site from southwest to

northeast, following the axis of the peninsula west of the divide flows to the northwest and the unnamed tributary to Little Mosquito Creek. Groundwater east of the divide flows towards Little Mosquito Creek and the adjacent marshlands. The two new data points provided by WFF16-GW6 and WFF16-GW7 have confirmed this interpretation by providing groundwater elevation points for the eastern part of the site. Groundwater originating at or flowing through the source area (near WFF15-GW7) flows generally northwest towards the unnamed tributary to Little Mosquito Creek. The horizontal hydraulic gradient beneath the WOD, as measured between WFF15-GW7, near the top of the peninsula, and WFF16-GW5, on the bank of the unnamed tributary, is 0.009.

Because of the nature of the contamination (petroleum), most of the wells at the WOD monitor the groundwater at or near the water table. Consequently, there is little information regarding the hydraulic head variation with depth. There is only one location, the WFF16-GW2 cluster, where two depths are monitored. WFF16-GW2S is screened from 9 feet to 19 feet, and WFF16-GW2D is screened from 23 feet to 28 feet below ground surface. On March 19, the groundwater elevations in WFF16-GW2S and WFF16-GW2D were 5.40 and 5.06 feet above msl, respectively, indicating a slightly downward vertical hydraulic gradient. The downward flow indicated by the vertical hydraulic gradient is expected to be impeded by the sea level clay layer.

To investigate the vertical component of groundwater flow beneath the WOD, a hydrogeological cross section was constructed from WFF15-MW3R, near the end of the runway, northwest to FTA-MW104S, on the opposite side of the unnamed tributary (see Figure 4-9). This cross section, presented in Figure 4-10 shows a predominantly vertical hydraulic gradient (downwards) at the top of the slope in the vicinity of wells WFF15-GW7 and WFF15-MW3R. Topographically downgradient, towards the unnamed tributary, the hydraulic gradient becomes progressively more horizontal, indicating flow towards the unnamed tributary. Immediately beneath the unnamed tributary, the hydraulic gradient is vertically upward in the shallowest groundwater (at and near the water table), which indicates groundwater discharge.

5.0 NATURE AND EXTENT OF CONTAMINATION

This section presents the results of the chemical analyses performed for surface soils, subsurface soils and groundwater samples collected during this Supplemental RI. In addition, historical data for these media will also be included in this evaluation.

The data are summarized in tables for each sampling medium and in tables comparing analytical results to corresponding background results. The latter tables summarize the occurrence and distribution of results for each chemical (frequency of detection, minimum result, maximum result, and location of the maximum result). The tabulated number of data points for each chemical varies depending on the number of results that were qualified as rejected or non-detected due to blank contamination as part of the data validation process. Individual sample results are presented in a complete database format in Appendix A.

5.1 USE OF HISTORICAL ANALYTICAL DATA

The work plan for the Supplemental RI (TtNUS, 2003a) and Sections 3.2 and 3.4 of this report detail the historical investigations and results at the WOD. As presented in the previous sections, the 2001 RI included the collection and analysis of samples from the area of stained soils and select monitoring wells. The usability of the data and a summary of results for each medium are discussed in this section.

5.1.1 Data Usability

Analytical data from the 2001 RI were verified as to validation status and the interpretation of qualifiers attached to individual results. Data qualified as rejected (R) or false positives attributable to blank contamination (B) were removed from further consideration. Data qualified as estimated (J) or biased high (K) or low (L) were retained. An assessment of data usability was performed to determine if detection limits were adequate to meet the project objectives defined in the work plan (TtNUS, 2003a). A review of the 2001 RI data for the WOD indicates that these data are acceptable.

5.1.2 Surface Soils

Twenty-one surface soil samples were collected from the WOD during the 2001 RI. The validated analytical results for these samples are included in Appendix A. Table 5.1 presents a summary of analytical results for these samples (2WFF16-SB1S1 through 3WFF16-SS17) and the surface soil samples collected during the Supplemental RI. The sampling locations for the 2001 RI are shown in Figure 3-4. All of the 2001 RI surface soil samples were collected from the area of stained soil and

stressed vegetation. The results for these samples will be considered in evaluating the nature and extent of contamination at the WOD and in assessing human health and ecological risks.

Although the 2001 RI included an assessment of human health risks, the risk assessment did not take into consideration current EPA and VADEQ risk assessment guidelines and did not include a complete set of exposure scenarios. For the Supplemental RI human health risk assessment (HHRA), the 2001 RI data will be combined with the data from the Supplemental RI, and the combined data set will be used in risk assessment. In addition, the data will be evaluated to determine if an area of elevated risk or "hot spot" exists.

The 2001 RI included an assessment of ecological risks that applied appropriate EPA and VADEQ guidelines and is considered acceptable. For the Supplemental RI ecological risk assessment (ERA), the 2001 RI data will be combined with the Supplemental RI data into one data set and the data set will be compared to the 2001 RI data. The purpose of the comparison is to see if the combined data set is similar or different from the 2001 RI data set. An ERA using the surface soils will only be performed if the combined data set indicates a higher level of contamination considering the Supplemental RI sample results.

5.1.3 Subsurface Soils

Four subsurface soil samples were collected during the 2001 RI from four borings (SB1 through SB4) advanced at the WOD. The soil borings were located within and immediately adjacent to the stained area and downgradient of monitoring well WFF15-GW7, which exhibited high levels of contamination in earlier investigations. Samples were collected from the base of the four borings at depths ranging from 19 to 24 feet below ground surface. The validated analytical results for these samples are contained in Appendix A. A summary of analytical results for these samples (2WFF16-SB1S2 through 2WFF16-SB4S2) and the subsurface soil samples collected during the Supplemental RI are presented in Table 5.2. The sample locations are shown on Figure 3-4. The results for these samples will be considered in evaluating the nature and extent of contamination at the WOD and in assessing human health risks. Because these samples were collected at depths greater than 2 feet below the ground surface, they do not present a risk to ecological receptors and will not be considered in the ERA.

5.1.4 Groundwater

Nine monitoring wells were sampled during the 2001 RI. The sampling occurred on four occasions from April 1997 through February 2000. No single round of sampling included all nine wells. Monitoring wells MW-3, WWF15-GW1, and WWF15-GW7 were sampled in April 1997 and March 1998 (see Figure 3-4).

In May 1998, wells WFF16-GW1, -GW2S, -GW2D, -GW3, -GW4, and -GW5 were sampled. The final round of sampling was conducted in February 2000 and included the same six wells sampled in May 1998 plus well WFF15-GW7. Data from the four sampling events were pooled into one database and used for evaluating site characteristics in the 2001 RI (Versar Inc., 2001a).

Three additional monitoring wells were installed during the Supplemental RI to augment the existing monitoring points. These new wells and 10 existing wells were sampled in March 2003 and provide the most recent and most comprehensive data set available for the WOD. Because the analytical data from the 2001 RI were collected over a 3-year period using varying sampling methods, represent a less complete data set, and do not represent current conditions, the historical data will not be used for risk assessment purposes. The historical data will be used only for qualitative discussions of apparent contaminant patterns over time.

5.2 COMPILATION OF HISTORICAL AND SUPPLEMENTAL RI DATA

The Supplemental RI was performed to fill the data gaps identified in the work plan (TtNUS, 2003a). The Supplemental RI data, combined with the acceptable historical data discussed above, form the complete data set to evaluate the nature and extent of contamination and determine risks to human health and the environment. The sample analytical results presented in Appendix A of this Supplemental RI contain the results from the historical data combined with the Supplemental RI data.

5.2.1 Supplemental RI Data Usability

All analytical data from the Supplemental RI were validated following EPA Region 3 and national functional guidelines. Data qualified as rejected (R) or false positives attributable to blank contamination (B) were removed from further consideration. Data qualified as estimated (J) or biased high (K) or low (L) were retained. Appendix F contains the validation reports and support documentation for the Supplemental RI data. An assessment of data usability was performed to determine if detection limits were adequate to meet the project objectives defined in the work plan (TtNUS, 2003a). Based on the data usability review, the analytical data for the Supplemental RI are acceptable except for the instances stated above (data qualified B or R).

5.2.2 Surface Soils

Twenty-seven surface soil samples (WOD-SS-101 through WOD-SS-127) were collected from the WOD from February 6 through 21, 2003. The samples were collected, in general, based on an 80-foot grid pattern established across the site. Some field variations to the sampling locations were made to account

for suspected source areas as detailed in Section 4.2.1. Sampling locations are shown in Figure 4-3. Samples were analyzed for VOCs, SVOCs, PCBs, TAL metals, TOC, pH, and grain size.

Twelve marsh surface soil samples (WOD-SS-128 through WOD-SS-139) were collected from around the perimeter of the WOD from February 19 through 26, 2003. The samples were collected from the base of the embankment that forms the perimeter of the WOD site and in areas of runoff and deposition as detailed in Section 4.2.1. Sampling locations are shown in Figure 4-3. Samples were analyzed for VOCs, SVOCs, PCBs, TAL metals, TOC, pH, and grain size.

The 39 surface soil samples collected during the Supplemental RI combined with the 21 surface soil samples detailed in Section 5.1.2 form the data set to evaluate the nature and extent of surface soil contamination at the WOD. A summary of analytical results for the combined data set is presented in Table 5.1.

5.2.3 Subsurface Soil

Twenty-seven subsurface soil samples (WOD-SU-101-1315 through WOD-SU-127-0203) were collected from 27 borings from February 6, 2003 through February 26, 2003. The borings were advanced, in general, at locations based on an 80-foot grid pattern established at the site and in areas of suspected waste disposal. A description of the field program is presented in Section 4.2.2, and the sample locations are shown in Figure 4-5. The subsurface soil samples were collected from depths where evidence of waste materials was encountered or at mid-depth between the ground surface and the water table. Table 5.2 provides the depth for each sample. Samples were analyzed for VOCs, SVOCs, PCBs, and TAL metals.

The 27 subsurface soil samples collected during the Supplemental RI combined with the four subsurface soil samples detailed in Section 5.1.3 form the data set to evaluate the nature and extent of subsurface soil contamination at the WOD. A summary of analytical results for the combined data set is presented in Table 5.2.

5.2.4 Groundwater

The Supplemental RI field investigation included the drilling and construction of three new monitoring wells and the collection of groundwater samples from a total of 13 monitoring wells as detailed in Section 4.4. Monitoring wells sampled during the Supplemental RI are shown on Figure 4-7. The groundwater samples were obtained via low-flow sampling techniques following appropriate EPA Region 3 protocol and guidelines, and analyzed for VOCs, SVOCs, PCBs, TAL total and dissolved metals (field-filtered), and MNA

parameters (hydrogen, soluble manganese, nitrate, chloride, sulfate, methane/ethane/ethene, and TOC). Groundwater field parameters (pH, temperature, dissolved oxygen, ORP, salinity, conductivity, turbidity, alkalinity, ferrous iron, and hydrogen sulfide) were measured at each well.

The 13 samples collected during the Supplemental RI form the data set to evaluate the nature and extent of groundwater contamination at the WOD. Summaries of analytical results for the groundwater data set are presented in Table 5.3 and Table 5.4. As discussed in Section 5.1.4, historical groundwater sample results were used to formulate the CSM and are used for qualitative evaluation purposes and to support the evaluation of contaminant trends only.

5.3 BACKGROUND DATA COMPARISONS

5.3.1 Statistical Approach

Statistical methods presented in the WOD work plan (TtNUS, 2003a) were applied to compare the concentrations of substances detected in WOD samples to those found in background samples. Statistical methods adhere to published guidance (EPA, 2002a, 2000, 1998, 1996a, 1994a, 1994c, 1994d, 1992a, 1992b, 1989a, and 1989b; US Navy, 2000, 1999, 1998) and other literature references (Gilbert, 1993 and 1987; Gehan, 1965; and Millard and Deverel, 1988).

Section 4.1 of this report presents a discussion of the WOD background study conducted in 2003. Soil and groundwater data considered usable from the background study are applied in this section to compare to results from WOD samples and to evaluate whether compounds detected on site are related to site operations or attributable to background or anthropogenic conditions.

Background comparisons for metals were handled somewhat differently than background comparisons for organics. The background study found significant differences in metals concentrations between Bojac and Molena soil series and between surface and subsurface soil within the Molena soil series. Because the Molena soils predominate at the WOD, site-related surface and subsurface soil data for metals were statistically compared to background surface and subsurface soil data sets from the Molena classification. The background study revealed significant differences in concentrations of organic substances between surface and subsurface soil but not between the two soil series. Therefore, background organic data from the two soil types were consolidated to yield a larger surface soil data set that was statistically compared to WOD surface soil organic data. The background subsurface soil organic data were also consolidated from both soil types for comparison to WOD subsurface soil organic data.

The background study included approximately 10 samples of each background soil type, which was the stated goal in the WOD work plan to achieve adequate statistical power to detect small differences between background and site concentrations. However, individual circumstances for specific analytes can also impact statistical power, such as distributional shape, frequencies of detection, and whether the ranges of detection limits are low compared to the ranges of positive results, so statistical background test results for certain chemicals were qualified as not applicable on a case-by-case basis.

There were not sufficient upgradient groundwater samples to allow quantitative statistical comparisons to WOD site-related groundwater samples, so data were compared on a qualitative basis only. Appropriate background groundwater samples were limited to the wells upgradient of the WOD Site and only samples collected in 2003 were utilized because different groundwater sampling methods were used in earlier sampling rounds.

5.3.2 Data Pretreatment

Several data pretreatment steps were necessary prior to conducting statistical tests. For chemicals with at least one positive detection in each data set, a value of one-half the sample quantitation limit was assumed for non-detect (U qualified) results. Duplicate samples were averaged together and considered as one result. For duplicates, where one result was positive and the other result was a non-detect, the problem of calculating an average result arose whenever half the detection limit exceeded the positive result. In these situations, the positive result was used to represent the non-detect.

The WFF background study conducted in 2003 included screening for extreme values and anomalies. Findings were documented in the background study report. No suspect data were identified among the samples collected in the 2003 supplemental investigation, and data qualified unusable (R) or affected by blank contamination (B) were eliminated from consideration in this Supplemental RI.

Prior to conducting any background data comparisons, the underlying statistical distribution of data was determined for each detected chemical. The Shapiro-Wilk W-test or the Shapiro-Francia Test (EPA, 1992d) were performed to determine if the data set of chemical concentrations matched the shape of a normal or lognormal distribution. [The latter test is required if there are greater than 50 samples (EPA, 1992d, 1996a).] Normally distributed data exhibit a characteristic "bell-shape" curve that is symmetrical, whereas lognormal data have a skewed shape with a longer tail at the high-concentration end. For each analyte, the W-test was performed once using the original data and once after data was converted to their logarithms. A 5 percent level of significance was used to determine if the data deviated from either hypothesized distribution. Associated W-test scores greater than the critical value indicate that the

hypothesis of a normal or lognormal distribution cannot be rejected at a 0.05 level of significance, respectively.

The distributional shapes that were assumed in parametric background tests are listed in the background test results in Tables 5.5 and 5.6. W-test scores for distributional analysis tests for all substances detected in groundwater, surface soil, and subsurface soil are presented in Appendix G.

The shape of the data distribution determined which background comparison tests were applicable as summarized by the following decision scheme:

Case 1: If the W-test accepted the hypothesis of a normal distribution for both site and background, the parametric t-test as well as the set of nonparametric background comparison tests were conducted to decide whether site exceeded background.

Case 2: If the W-test rejected the hypothesis of a normal distribution for both site and background, but accepted the hypothesis of a lognormal distribution for both site and background, then only the set of nonparametric background comparison tests were conducted to determine that site exceeded background.

Case 3: If the W-test rejected both hypothesis of either a normal distribution or lognormal distribution for both site and background, then only nonparametric background comparison tests were conducted.

Special Cases for the upper tolerance limit (UTL) test: The UTL test was not used to decide globally that site exceeds background, but rather IF site data were first determined to exceed background based on the other statistical tests, then the information presented in the UTL test could be used to evaluate whether individual sample results might represent hot spots. If the W-test accepted the hypothesis of a normal distributional shape and the score reflected a better fit than for a lognormal shape, then the UTL test was based on the raw (not log-transformed) data. If the W-test accepted the hypothesis of a lognormal distributional shape and the score reflected a better fit than for a normal distribution shape, then the UTL test was based on the log-transformed data. If the W-test indicated that the data did not match either a normal or lognormal shape and there were at least 19 data points in the background data set, then the UTL was based upon substitution of the non-parametric 95^{th} quantile of the background data set.

5.3.3 Background Comparison Tests

To determine if results of samples from the WOD site are elevated relative to background sample results, an array of statistical procedures was applied that consist of three quantitative tests that look for overall differences between the entire populations of site and background data values; four quantitative tests that essentially look for hot spots; and two qualitative tests that examine only the frequency of detection (proportion of detected versus non-detected values in site versus background) but not the magnitude of values.

Each statistical test was run using a decision-making probability level (P-level) of 0.05, which means that, in situations where the test conclusion states that site-related results are greater than background, the chance of the test yielding a false conclusion caused by random variations in the data set is five percent or less. The overall conclusion (whether site results are greater than background) was assumed to be "yes" if any one of the quantitative tests concluded that site data are elevated above background. If no conclusion could be reached for any of the quantitative tests (e.g., if the assumptions necessary to run each of the various tests were not valid), then the overall decision was based on the conclusions of the qualitative tests alone. Further information regarding each statistical test is presented below:

- The means of the two data sets were compared if both site and background matched a normal distribution. If the site and background data exhibit equal standard deviations (based upon Bartlett's test for equal variances), then the student's t-test was applied; otherwise, Satterthwaite's t-test was performed to see if the site mean is greater than the background mean. The t-test is valid only if at least 85 percent of site data and 85 percent of background data are positive detects, there are at least three sampling points in each data set, and the pooled standard deviation is not zero.

- Nonparametric statistical tests, which do not require underlying assumptions regarding equal data distributions, were also applied in each case. The Mann-Whitney U-test was used to determine whether the site and background data are from populations with identical medians and rank distributions. The Mann-Whitney test involves combining the two data sets, ranking results from smallest to largest, and evaluating whether the two sites have a similar distribution of data within the range of low to high ranks. If more than 40 percent nondetected results were present in either the site or the background data set or when multiple levels of detection limits are present, a different statistically valid test, Gehan's test, was substituted because recent guidance (EPA, 1992c) indicates that the Mann- Whitney test is not valid in the aforementioned situations. (Gehan's test is statistically equivalent to the Mann-Whitney Test if all results are positive.) For either of these tests to work, not all data points can be tied and there must be at least two background data points. The Mann-Whitney U test and the Gehan test statistics were computed using appropriate score adjustments for tied

values and a normal approximation when sufficient data points were available; whereas, an exact computation of probabilities was used in the situations where there were very few (for example, less than eight) data points.

- A 95 percent upper tolerance limit (UTL) test was performed strictly to provide supplementary information to assist in locating potential hot spots of a magnitude exceeding 95 percent of the background population. Because the UTL test is designed to compare only one site-related sample to background, erroneous conclusions can occur if this test is relied upon when the site data consist of a larger number of samples, since in such cases the probability of one or more of the site-related samples exceeding the UTL is much greater than 5 percent even when the site and background data belong to the same underlying statistical population. Therefore, in accordance with Navy guidance, the UTL test was only considered as a source for qualitative information and other statistical tests were relied upon as the basis for decisions regarding whether the site population exceeds background.

- The 95 percent UTL is defined as the calculated upper limit that, on the average, is expected to include 95 percent of the background population (EPA, 1992a). If the background data were determined to match the shape of a normal or lognormal population, then the limit was calculated using the t-distribution or K-value and the appropriate normal or log-transformed mean and standard deviation from the background data set. For this test to be valid, the background data set is required to be comprised of at least 85 percent detects and at least three data points.

- A substitute procedure for the 95 percent UTL test, called the 95 percent quantile test, was employed to provide supplementary information to assist in locating potential hot spots if the background data were not in the shape of a lognormal or a normal population. For the quantile test to be valid, at least 19 background data points are required, no detection limit can be greater than the UTL, and at least 10 percent of the data points must be detects in the background data set.

- The upper ranks test (EPA, 1992c, 1996d) is another hot spot test. This test combines the site and background data into one set and determines whether the major portion of a subset of the largest detected results is comprised chiefly of site data rather than an equal mixture of site and background. In this procedure, the probability is calculated that k or more samples from the largest r data points in the combined data set are comprised of site data, assuming that the site and background populations are equal. In the event that there is less than a five percent chance that this could happen if the populations are indeed the same, then the test concludes that there is a hot spot comprised of samples from the area of interest. This test was used for making decisions regarding background.

- In the event that none of the above quantitative statistical tests yielded a definite "yes" or "no" decision, a test of proportions was used to determine if the percentage of positively detected results is greater in the site data versus the background data. When only a very small portion of results are detected (less than 10 percent), this test is recommended (EPA, 1996d, 1989b). The test is routinely applied using a normal distribution approximation to the probability that site is above background but is not considered valid when fewer than five samples are detected in either site or background. To reach a confident decision in such cases, a generalized version of the test of proportions, called the Fisher Exact Test, is required (Brownlee, 1965). This test was applied to all situations because it calculates the exact probability for all combinations of possible outcomes and gives a probability level for the condition where the observed frequency of site detects is greater than background, given the number of samples involved.

The following provides a breakdown of the decision scheme applied to determine which statistical tests were used:

Case 1: If the W-test accepted the hypothesis of a normal distribution for both site and background, then the W-test using the logarithmic conversion was not applicable and parametric as well as nonparametric background comparisons were conducted.

- For this case, the parametric t-test was performed to compare the arithmetic means of site and background only if there were greater than 85 percent detects in the site data and greater than 85 percent detects in the background data. A Satterthwaite adjustment of the t-test was used if the standard deviations between site and background data were found to be significantly different from one another (criteria based on Bartlett's Test for equal variances).

- For Case 1 (but also applicable to Cases 2 and 3, as discussed later), a nonparametric test was also selected to compare the ranks of the overall populations, based on either the Mann Whitney test or Gehan's test. The prevalence and magnitude of non-detects can bias the outcome of the Mann Whitney test, but not so for Gehan's test. Therefore, Gehan's test replaced the Mann Whitney test if any of the following circumstances occurred:

  a. if more than 40 percent non-detects were present in either the site data set or the background data set;

  b. if the number of non-detect data points from the site data that are greater than either data set's lower 25^{th} percentile for positive detections is greater than 10 percent of the total number of detects in the site data;

c. if the number of non-detect data points from the background data that are greater than either data set's lower 25th percentile for positive detections is greater than 10 percent of the total number of detects in the background data;

d. if the ratio of the highest detection limit to the lowest detection limit among all data groups combined was greater than 3.5;

e. if greater than 15 % of the data points in the site data set consisted of non-detects that were less than the 25th percentile of the subset of non-detected site data but greater than the 25th percentile of the subset of non-detected background data (a relative shift in the distribution of the two data sets' non-detects occurring in a low percentile range). The same test was also performed for the converse situation (more than 15 percent of background data consist of nondetects whose magnitude was less than the 25th percentile of non-detected background data but greater than the 25th percentile of non-detected site results). The same tests were also performed at the 75th percentile and 95th percentile of site and background data sets, such that evaluating all of these tests together served to identify any significant shifts in the relative distribution of non-detects compared between the site population and background population.

- Technically, although Gehan's test could be substituted for the Mann Whitney test in all circumstances, the Mann Whitney test is more familiar to scientists and available in software, so the use of the Mann Whitney test has been retained because it is easier for a third party to independently verify the calculations and test results.

- For Case 1 (but also applicable to Cases 2 and 3, as discussed later), a second nonparametric test was selected to compare the upper ranks (i.e., the upper percentiles) of the site data versus background data. This test has been labeled as "upper ranks" to avoid confusion with a separate test for upper tolerance limits (UTL) that also involves quantiles for the nonparametric case. The term "quantile test" is also used for the upper ranks test. This test was computed multiple times, starting with the highest concentration (rank) data points, and then repeating the test after including the next lower concentration sample results, thereby successively expanding the size of the upper rank subsets to include lower percentiles of the combined site and background data. The upper ranks tests were concluded when the highest non-detected result was encountered or when the maximum size subset of site data was found that had at least a probability (P-level) of 0.05 that the upper ranks of this subset of data is significantly greater than background.

- For Case 1 (but also applicable to Cases 2 and 3, as discussed later), if each of the applicable test results (t-test, Mann Whitney, Gehan, and Upper Ranks) were considered not applicable ("NA") due to insufficient sample size or other limitations, then a test of proportions was considered applicable to determine if the percentage of positively detected results was statistically greater in the site data versus the background data. The test of proportions was performed one of two ways, either based upon combinatorial probabilities calculated using Fisher's exact test if there were less than 5 detects in the site data set, less than 5 detects in the background data set, less than 5 non-detects in the site data set, or less than 5 non-detects in the background data set. If there were 5 or more detects and non-detects for each data set, then a normal approximation to the probability of proportions was computed using the z-test. These results were used to decide site is greater than background only if other tests were "NA".

- For Case 1, if a decision was first reached that site concentrations were greater than background based on the tests presented earlier, then the 95 percent upper tolerance limit (95 % UTL) was considered applicable. The UTL test was not used to decide globally that site exceeds background, but rather IF site data exceeded background, then the information presented in the UTL test could be used to evaluate whether individual sample results might represent hot spots. Following previous risk assessment recommendations from EPA Region 3, the UTL was computed in two different ways, using formula presented in EPA, 1992a: In the case where there were less than 8 samples in the background data set, the UTL was calculated assuming a 50 percent coverage of the 95 percent UTL, so that formula included the student's t-value times the standard deviation. In the case where there were 8 or more samples in the background data set, the UTL was then calculated in a more conservative manner assuming 95 percent coverage of the 95 percent UTL, so that the formula included the K-value times the standard deviation. Note that the UTL test has an unacceptable rate of false positives if there are many site samples, and the existence of one or more exceedances in a data set comprised of more than three site samples does not by itself necessarily indicate that site exceeds background.

Case 2: If the W-test rejected the hypothesis of a normal distribution for both site and background, but accepted the hypothesis of a lognormal distribution for both site and background, then only the set of nonparametric background comparison tests were conducted to determine that site exceeded background. The following tests were performed for Case 2:

- Either the Mann Whitney or Gehan's test was performed, as discussed above.

- The upper ranks test was performed, as discussed above.

- The t-test was not performed.

- The test of proportions was performed and considered in making decisions only if the Mann Whitney, Gehan, and upper ranks tests were all not applicable ("NA").

- If a decision was first reached that site concentrations were greater than background based on the tests presented earlier, then the 95 percent upper tolerance limit (95 % UTL) was considered applicable. The UTL test was not used to decide globally that site exceeds background, but rather IF site data exceeded background, then the information presented in the UTL test could be used to evaluate whether individual sample results might represent hot spots.

Case 3: If the W-test rejected both hypothesis of either a normal distribution or lognormal distribution for both site and background, then only nonparametric background comparison tests were conducted. The following tests were performed for Case 3:

- Either the Mann Whitney or Gehan's test was performed, as discussed above.

- The upper ranks test was performed, as discussed above.

- The t-test was not performed.

- The test of proportions was performed and considered in making decisions only if the Mann Whitney, Gehan, and upper ranks tests were all not applicable ("NA").

- If a decision was first reached that site concentrations were greater than background based on the tests presented earlier, then the 95 percent upper tolerance limit (95 % UTL) was considered applicable. The UTL test was not used to decide globally that site exceeds background, but rather IF site data exceeded background, then the information presented in the UTL test could be used to evaluate whether individual sample results might represent hot spots. In this case, the UTL test was based upon the non-parametric 95^{th} quantile and was only possible if there were at least 19 data points in the background data set.

For this project, computer algorithms were employed to automatically perform applicable statistical tests wherever the necessary underlying assumptions are valid. This approach allows the use of any valid test result that identifies that concentrations from one data set are elevated, regardless of the outcome of unrelated statistical tests.

5.3.4 Surface Soil Background Comparison Results

Table 5.5 compares the WOD site-related data to background for surface soil. Surface soil data were demonstrated to be above background for sodium and bis(2-ethylhexyl) phthalate. With sodium, the Mann Whitney test revealed that there was an overall difference in the relative ranks of the site and background populations, which has a probability of occurring only 0.9 percent of the time in statistically equivalent populations. However, because data did not follow a normal or lognormal distribution the means of the two populations could not be directly compared. The upper ranks test essentially corroborated the same findings and indicated all 27 of the sodium sample concentrations in the site data set were greater than any values in the background data set, which has a probability of occurring only 0.07 percent of the time in statistically equivalent populations.

In the case of bis(2-ethylhexyl) phthalate, Gehan's test indicated that there was an overall difference in the relative ranks of the site and background populations, which has a probability of occurring only 0.4 percent of the time in statistically equivalent populations. However, because data did not follow a normal or lognormal distribution the means of the two populations could not be directly compared. From a qualitative standpoint, the frequency of detection was approximately 40 percent for site data versus only 8 percent for background data, with 17 out of 25 WOD sample results greater than sample quantitation limits.

Surface soil background test results were inconclusive for antimony, silver, and most of the organic compounds detected. In most cases, this was due to the majority of samples being nondetected, which reduced the effective size of the data sets that were compared. In the case of silver, several site and background results were qualified as rejected and certain site results were qualified due to blank contamination, which further reduced the number of usable data points.

5.3.5 Subsurface Soil Background Comparison Results

Table 5.6 compares the WOD site-related data to background for subsurface soil. No substances detected in subsurface soil were demonstrated to be above background. Subsurface soil background test results were inconclusive for antimony, cadmium, cyanide, selenium, silver, thallium, and most organic compounds. Generally, this was due to many of the results being nondetected (and in few cases qualified due to blank contamination or rejected), which reduced the effective size of the data sets that were compared.

5.4 NATURE AND OCCURRENCE OF CONTAMINATION

5.4.1 Surface Soil

Results from the background tests, as shown in Table 5.5, indicate that a limited number of contaminants were detected in samples collected from the WOD surface soils at levels exceeding background levels. No metals were identified as exceeding background concentrations. However, tests were inconclusive for antimony and silver. As shown in Table 5-7, antimony was not detected in the background samples but was detected in two WOD site surface soil samples. Antimony was detected at levels near the detection limit in samples 3WFF16-SS13 (0.92 mg/kg) and WOD-SS-106 (0.36 mg/kg). Both of these samples were collected near the northwestern end of the stained soil area (see Figure 5-1).

Silver was detected in 28 of the surface soil and marsh soil samples collected from the site. The maximum concentration 2.3 mg/kg was detected in sample WOD-SS-136. This is a marsh soil sample collected from the western drainage area leaving the WOD site. Similarly, sample WOD-SS-135, a marsh soil sample collected in the northwestern drainage area, was the only other sample with a silver concentration greater than 1 mg/kg (1.6 mg/kg). Figure 5-1 illustrates the positive detections of silver in the WOD site surface soil samples. As can be seen, the remainder of the positive detections are similar to background silver concentrations (0.15 mg/kg to 0.3 mg/kg).

Bis(2-ethylhexyl)phthalate is the only organic compound identified as exceeding background levels. The highest level of bis(2-ethylhexyl)phthalate detected (2,800 ug/kg) was in sample 3WFF16-SS9. This sample was collected during the 2001 RI and was located within the stained soil area. Seventeen of the other 20 surface soil samples collected during the 2001 RI also contained somewhat elevated levels (430 ug/kg to 2,100 ug/kg) of bis(2-ethylhexyl) phthalate. Only 8 of the 39 surface soil samples collected during the Supplemental RI contained bis(2-ethylhexyl) phthalate and the levels were at low estimated concentrations (40J ug/kg to 170J ug/kg). Figure 5-1 illustrates the positive detections for bis(2-ethylhexyl) phthalate in the WOD surface soil samples.

Background tests were inconclusive for most other organic compounds. PCBs were detected at estimated trace levels in samples WOD-SS-135 and -136 (220J ug/kg and 180J ug/kg, respectively). No other PCBs were detected on site. Benzaldehyde, which was not analyzed for in the background samples or in the 2001 RI samples, was detected in 20 Supplemental RI samples at estimated concentrations ranging from 46J ug/kg to 1,500J ug/kg. The low levels and widespread occurrence of benzaldehyde does not appear to be indicative of waste disposal activities at the WOD.

Other organic compounds were infrequently detected in WOD surface soils, and few samples contained SVOCs at concentrations greater than maximum background concentrations. Benzo(a)pyrene was detected in nine WOD samples at concentrations ranging from an estimated 47J ug/kg to 1,300 ug/kg. The maximum level was detected in sample 3WFF16-SS10. This sample was collected during the 2001 RI from the stained soil area. Other benzo(a)pyrene detections greater than the maximum background concentration (410J ug/kg) were reported in samples 3WFF16-SS9 and WOD-SS-123 (910 ug/kg and 550J ug/kg, respectively). Sample 3WFF16-SS9 was collected from the western edge of the stained soil and sample WOD-SS-123 was collected immediately south of this area, toward the end of the active runway. Figure 5-1 provides the location and concentrations of benzo(a)pyrene detections in the WOD surface soil samples. A similar pattern, as shown on Figure 5-1, is seen for benz(g,h,i)perylene concentrations.

VOCs were detected at trace levels in only a few WOD surface soil samples. The 2001 RI identified benzene, toluene, 1,2-DCE, and ethylbenzene as the VOC groundwater contaminants at the WOD. Benzene and 1,2-DCE were not detected in surface soil samples, and toluene and ethylbenzene were detected only at trace levels (2J ug/kg) in two soil samples.

5.4.2 Subsurface Soil

Background tests for subsurface soils, as shown in Table 5.6, indicate that no metals were identified as exceeding background levels. Tests were inconclusive of antimony, cadmium, cyanide, selenium, silver, and thallium. The maximum site concentrations for antimony (18.3 mg/kg), cadmium (23.4 mg/kg), silver (389 mg/kg) and thallium (3.5 mg/kg) were detected in sample WOD-SU-111-0507 (see Figure 5-2). This sample, as described in Section 4.2.2.2, was collected from a layer of fill material encountered in boring WOD-SB111. Antimony was not detected in any other subsurface sample. Cadmium was detected in only three other WOD subsurface soil samples, and the concentrations in these samples were within the background range of 0.19 mg/kg to 0.57 mg/kg. Figure 5-2 provides the locations and concentrations of cadmium detections in WOD subsurface soil samples. Similarly, silver was detected seven other subsurface soil samples at levels approximating background levels. The only other on-site detection of thallium (0.18 mg/kg) is less than background levels (0.22 mg/kg to 0.53 mg/kg).

The background tests were inconclusive for cyanide and selenium due to the low frequency and level of detections in both background and site subsurface soil samples. Cyanide was not analyzed for during the Supplemental RI but was detected in one 2001 RI sample at 0.59 mg/kg. Selenium was detected in only two WOD subsurface soil samples at concentrations of 0.34 mg/kg and 0.35 mg/kg. These detections are within the range of selenium concentrations, 0.23 mg/kg to 0.89 mg/kg, detected in background subsurface soils.

Background tests were inconclusive for all organic compounds except bis(2-ethylhexyl)phthalate. The tests indicate that site subsurface detections (37J ug/kg to 190J ug/kg) are similar to the levels found in background subsurface soils (37J ug/kg to 110J ug/kg). As shown in Table 5-8, most organics were infrequently detected in the WOD subsurface samples. The maximum concentration of organics, and most of the positive detections, were in samples collected in close proximity to the stained soil area (see Figure 5-2). This contaminant pattern is consistent with the observations made during the soil boring and sampling phase of the Supplemental RI. Evidence of contamination in this area was noted during field activities in the form of elevated PID readings, fuel-like odors, and the presence of a petroleum sheen or product layer at the water table.

5.4.3 Groundwater

As can be seen in Table 5.9, the maximum concentrations of potential groundwater contaminants were identified, with few exceptions, in monitoring wells WFF15-GW7 and WFF16-GW2S/D. In addition to the highest levels of contamination, organic contaminants were almost exclusively detected only in these two wells.

Arsenic was detected (21.4 ug/L) only in a sample collected from monitoring well WFF16-GW2D. The filtered groundwater sample collected from this well, WOD-WFF16-GW2DF, also contained arsenic at 19.5 ug/L. The maximum barium concentration, 117 ug/L, was detected in the shallow monitoring at this same location (WFF16-GW2S). Barium was detected site wide and in site-specific background wells. Only one site-specific background well exists at the WOD (WFF15-MW3R), and the level of barium detected in a sample from that well was less than all site detections. However, as shown in Table 4.5, base-wide barium levels appear to be similar to the range detected in the WOD monitoring well samples.

Chromium was detected in three WOD monitoring wells (WFF16GW1 and -GW3, and MW4) at levels ranging from 6.1 ug/L to 147 ug/L. The locations and concentrations of chromium detections in monitoring well samples are shown on Figure 5-3. As shown in Table 5.4, chromium was also detected (43.5 ug/L) in the filtered sample collected from monitoring well WFF16-GW1 but not in the other two wells. Monitoring wells WFF16GW1 and -GW3 were not developed during the Supplemental RI due to the lack of water, see Section 4.4.1. In addition, samples from MW4 were reported to be brown colored and the turbidity measurements in this well remained high after purging. Lead was also detected (5.1 ug/L) in the unfiltered but not the filtered sample from this well. The only other lead detection was in the samples collected from monitoring well WFF15-GW7 (68.6 ug/L total lead and 54.7 ug/L dissolved lead). Iron and manganese levels were high in both the unfiltered and filtered samples from this well.

Iron and manganese levels appear to be elevated in most wells when compared to the site-specific upgradient well (WFF15-MW3R). However, the WOD wells are shallow wells and most remained slightly turbid even after development and purging. In addition, the levels detected at the WOD (iron from 50.6 ug/L to 49,900 ug/L; manganese from 14 ug/L to 641 ug/L) are similar in range to the base wide data (iron from 452 ug/L to 50,000 ug/L; manganese from 4.5 ug/L to 3,110 ug/L) for other monitoring wells located at the facility, see Table 4.5.

Organic contamination was almost exclusively detected in a sample collected from monitoring well WFF-GW7. The levels of organic contamination detected in Supplemental RI groundwater samples and the location of the samples are shown on Figure 5-3. Poly aromatic hydrocarbons (PAHs) and VOCs were detected at the highest occurrence and concentrations in the sample collected from well WFF15-GW7. This well is located in the center of the stained area identified as the suspected source area during the 2001 RI. Based on the data from the other WOD monitoring wells, it appears that the contamination is generally limited to this well, with low levels identified in downgradient monitoring wells WFF16-GW2D and WFF15-GW1 and -GW2. This can be illustrated by examining the total benzene, ethylbenzene, and xylene (BTEX) concentrations found in WOD monitoring wells. BTEX was detected at 740 ug/L in WFF15-GW7, 16ug/L in WFF16-GW2D, 2 ug/L in WFF15-GW2, and was not detected in WFF15-GW1. Additionally, no BTEX compounds were detected in a sample collected from monitoring well WFF16-GW5, located northwest (downgradient). No BTEX compounds were detected in the shallow well, WFF15-GW2S, located adjacent to WFF15-GW2D. Trace levels of Cis-1,2-DCE (1 ug/L) were detected in this shallow well. Similar levels were detected in the deep well, WFF16-GW2D (2 ug/L), WFF15-GW7 (1 ug/L), and WFF15-GW1 (3 ug/L).

No contaminant plume delineation, or isoconcentration, mapping has been attempted using the Supplemental RI data because the results indicate that significant contamination is limited to the small area bounded by monitoring wells WFF15-GW7 and WFF16-GW2D. This is similar to the findings presented in the 2001 RI (Versar, Inc., 2001a). As presented in Section 3, the RI groundwater data set consisted of partial rounds of monitoring samples collected over a 3-year period. Three samples were collected from WFF15-GW7 and two samples were collected from WFF16-GW2S/D, WFF16-GW5 and WFF15-GW1 over the 3-year period from April 1997 through February 2000. BTEX compounds were detected only in the samples collected from WFF15-GW7 and WFF16-GW2D. Total BTEX levels ranged from 653 ug/L to 2,780 ug/L in WFF15-GW7 and from 63 ug/L to 73 ug/L in WFF16-GW2D. BTEX compounds were not detected in any of the downgradient well samples collected during this period.

5.5 REFINED CONCEPTUAL SITE MODEL

The additional hydrogeological and chemical data obtained during the Supplemental RI were used to revise the CSM as presented in this section. The revised CSM was derived through the integration of the updated hydrogeological interpretation of groundwater flow (discussed in Section 4) with the nature and extent of contamination based on results from the Supplemental RI sampling and select previous data.

The site is underlain by the Columbia Group and the Yorktown Formation, which comprise the two aquifers beneath the WOD. The Columbia aquifer is the aquifer of concern because, although no borings at the WOD are sufficiently deep to penetrate the underlying Yorktown Formation, the regional geology and the site investigations performed elsewhere on the MB (including the adjacent FFTA) indicate that the underlying Yorktown aquifer is hydraulically isolated from the Columbia by a confining clay unit or aquitard. The Columbia aquifer extends from the land surface to the top of the Yorktown aquitard, or to an estimated subsurface depth of approximately 50 feet.

The hydrogeologic conclusions and the interpretation of the revised CSM generally agree with the conclusions presented in the 2001 RI (Versar, Inc., 2001). The Columbia Group at the site consists chiefly of fine- to medium-grained sands, with lesser amounts of silt and clay. A sequence of finer-grained sediments was encountered at an elevation near sea level in the majority of borings drilled during both the 2001 RI and this Supplemental RI (see Appendices D and E for the boring logs). This layer varied in lithology from a clayey sand to a silty clay to clay, with a typical thickness ranging between one to two feet. A similar fine-grained layer (referred to as the Sea Level Clay, or SLC) has also been encountered near an elevation of sea level at the adjacent FFTA Site (TtNUS, 2003a), suggesting this unit may have at least a semi-regional extent. However, at the WOD this SLC was significantly absent from the boring for monitoring well WFF15-GW7 (which was drilled in the source area), although it was detected in the neighboring borings.

Groundwater at the WOD has been interpreted to flow in directions ranging through an arc of approximately 180 degrees, or from nearly due west, through northward, to nearly due east. These interpreted flow directions are consistent with the flow directions defined during previous investigations, and are also consistent with the directions that are predicted from the surface topography of the WOD, which is located on a small peninsula that extends northward from the end of Runway 17-35 towards Little Mosquito Creek and its associated lowlands and wetlands. The hydrogeologic cross-section (see Figure 4-10) indicates that the vertical hydraulic gradient across the site is variable and ranges from a downward orientation within the areas of higher elevation (recharge zone), to a horizontal to possibly upward orientation within the lowland areas at the base of the peninsula (discharge zone).

Contamination at the WOD exists in both the soil and groundwater medium, but the extent of contamination is generally localized and concentrated in two geographic areas. A localized zone of fill material was identified in the west-central portion of the site, at boring locations SB110 and SB111 (see Figure 4-5). Samples from the fill material (especially from SB111, see Figure 5-2) contained elevated concentrations of metals and some organic compounds, primarily PAHs and BTEX components. The limited presence to absence of groundwater contamination immediately downgradient of the area of fill at WFF16-GW3, -GW4, and -GW5 (see Figure 5-3) indicates that this fill material is not significantly impacting the quality of the local groundwater.

The other area of localized contamination exists within an area of "stained" surface soil and stressed vegetation (as noted during the 2001 RI) located in the vicinity of monitoring well WFF15-GW7. Surface soil, subsurface soil, and groundwater within this area contained elevated concentrations of some metals and many organic compounds, primarily PAHs and BTEX compounds. The vertical distributions of the organic compounds within the soil (as determined by both the analytical chemistry and the PID readings measured during the Supplemental RI) are somewhat atypical. Relatively high concentrations of contamination were encountered just above the water table, relatively low levels were encountered at the surface, and the intervening soil horizons were relatively free of contamination. Conceptually, if the contamination were introduced at or near the surface, then the highest levels of soil contamination (especially for the less mobile PAHs) would be expected near the surface or the shallow subsurface horizon. Even if the compounds had migrated with infiltrating precipitation to the water table over time, significant concentrations of residual contamination would be expected in the intervening subsurface soil. The presence of highly contaminated soil at the water table and the lack of contamination in the overlying soil leads to the possibility that the compounds were either introduced directly into the deeper horizon through excavation and disposal or migrated on the surface of the water table from an upgradient source and were deposited within the soils as a smear zone created by fluctuations in the water table. The lack of shallow contamination noted in the immediately upgradient soil boring SB-102, and the lack of any contamination in the adjacent borings SB-121, -122, and -123 (see Figure 5-2) preclude the existence of a significant upgradient contaminant source. Under either hypothesis, there does not appear to be a connection between the deeper contamination and the lower levels of soil contamination observed on the present surface soils.

Groundwater contamination at the WOD is very localized and is centered in the vicinity of monitoring well WFF15-GW7. This well was constructed with a 15-foot screen that extends across the water table to a depth below the expected depth interval for the SLC, which was not noted at this location. The current and historical sampling of this well has indicated that significant groundwater contamination exists at the water table. In addition, a floating layer of petroleum product (0.4 foot thick) was measured in this well at the start of the current field activities. The presence of a free-phase product and the high concentrations of

contamination detected in the dissolved phase within the groundwater indicate that the contaminant source occurs at or near the water table in the immediate vicinity of WFF15-GW7.

The data obtained from other soil borings in the vicinity of WFF15-GW7 indicate that the source is relatively small and discrete, because it is bounded in both the adjacent upgradient and sidegradient directions by borings from which neither contaminated soils nor elevated PID readings were detected near the water table. Groundwater analytical results also indicate the localized presence of contamination. Total groundwater BTEX concentrations viewed with the hydrogeologic cross-section constructed for the WOD (see Figure 5-4) indicate that the groundwater plume emanating from this source area migrates downward within the aquifer but attenuates rapidly in the downgradient direction. Very low concentrations of a few VOCs and no SVOCs were detected in the downgradient deep well (WFF16-GW2D), and no organic compounds at all were detected in the downgradient shallow well (WFF16-GW2S). The presence of the hydrocarbon plume in WFF16-GW2D (albeit at low levels) at a depth below the SLC, and the absence of the plume above the SLC in WFF16-GW2S, appear to confirm the observation that the SLC is not present in the immediate vicinity of the source area, which allows the plume to migrate to a depth below the SLC. If an effective aquitard existed at the WOD, the plume would be expected to exist above, but most likely not below, the SLC.

The limited geographic extent of the groundwater plume is interpreted to be a result of several factors. The first factor is the mobility of the contaminants. Many of the contaminants at the source area are SVOCs, which are relatively immobile in groundwater, and are not expected to migrate significant distances from the source area. However, the abundant VOCs detected at the source area are relatively mobile in groundwater and could reasonably be expected to be present in the downgradient well (WFF16-GW2S/D) given the elapsed time since the contaminants were introduced at the source. Therefore, the mobility of the contaminants alone cannot explain the limited areal extent of the plume.

The second factor believed to be attenuating the plume is the biodegradation of the organic contaminants. Various MNA parameters collected during the Supplemental RI (including dissolved oxygen, ORP, and methane) support the interpretation that active biodegradation is occurring within the plume. Significant observations noted from the evaluation of the MNA parameters include the following:

- The groundwater plume corresponds with a zone of very low (nearly depleted) dissolved oxygen levels in wells WFF15-GW7 and WFF16-GW2D, suggesting that significant aerobic biodegradation has occurred in this area. Although low dissolved oxygen concentrations were also measured in several downgradient wells (including WFF15-GW1 and WFF16-GW7), it is believed that the low oxygen levels at these locations are reflecting the high organic content of the marsh and palustrine environments of the lowlands surrounding this site. The very low dissolved oxygen concentrations found at the source

area are markedly dissimilar from the surrounding, more oxygenated waters that were sampled from similar higher site elevations.

- The groundwater plume corresponds with a groundwater zone characterized by very weakly oxidizing (ORP of 3) to strongly reducing (ORP of -51) conditions. Reducing conditions were also measured in several downgradient wells located in the site lowlands, but these readings are believed to reflect the natural groundwater conditions at these locations. The weakly oxidizing to reducing conditions measured at the source area are markedly dissimilar from the surrounding, strongly oxidizing conditions noted in the adjacent wells from the higher site elevations.
- The groundwater plume corresponds with a zone of elevated methane concentrations, suggestive of a zone of methanogenic biodegradation. Elevated methane concentrations were also noted in several downgradient wells located in the site lowlands, but these readings are believed to reflect the natural groundwater conditions at these locations. The elevated methane concentrations detected at the source area are markedly higher than those detected in the adjacent wells from the higher site elevations.

The third factor that is believed to be inhibiting the migration of the plume is the hydraulic conductivity of the aquifer, although a relative lack of data (and the conflicting nature of the data that do exist) make this connection less certain. Aquifer tests conducted during the 2001 RI (Versar, Inc., 2001a) indicate that the hydraulic conductivity of the Columbia Aquifer at the WOD is in the magnitude of 5E-4 cm/sec, which is on the low end of the range of values obtained across the MB, but is sufficiently high to permit the migration of the plume to the groundwater discharge points surrounding the WOD. However, the two wells tested in conjunction with the WOD 2001 RI were WFF15-GW1 and WFF15-GW2, which are located west of the peninsula in the lowlands adjacent to the unnamed tributary to Little Mosquito Creek. It is possible that the hydraulic conductivity of the aquifer within the higher elevations of the peninsula (in the vicinity of the plume) are lower, although the lithologies noted during the drilling of the soil borings are consistent with those found elsewhere (predominantly sands), and are not suggestive of lower-conductivity material. However, the aquifer properties noted during the recent sampling event are not consistent with the properties that would be expected from the observed lithologies. Several of the wells exhibited very slow recharge rates that are indicative of a bcally low transmissivity, even though sands were the dominant aquifer material. It is possible that the multiple episodes of excavation and filling have created a heterogeneous aquifer whose properties may vary within short lateral distances. For a given hydraulic gradient and effective porosity, a lower hydraulic conductivity will result in a lower groundwater velocity, which will also allow the MNA processes to impact the groundwater for a greater period of time per unit distance traveled.

A comparison of the contaminant concentrations detected during the Supplemental RI with those detected historically at this site (Versar, Inc., 2001a) indicates that overall, the most recent concentrations are within

the same order of magnitude. The presence of weathered product indicates a significant volume of source material still remains, but it appears that the various processes of biodegradation are effectively attenuating or restricting the lateral extent of the dissolved-phase plume.

6.0 FATE AND TRANSPORT

Several aspects of contaminant fate and transport relevant to the WOD are discussed in this section. The ultimate fate of chemicals in the environment is determined by several physical, chemical, and/or biologically related factors. The role that physical properties such as specific gravity, solubility, and vapor pressure play in determining the processes that take place for a particular chemical (or class of chemicals) is often variable and can vary considerably from location to location, even within the same contaminant regime. Chemical and biological transformational processes can also be significantly affected by localized conditions.

Various chemical and physical properties affecting contaminant migration and the media (e.g., geologic influences) that affect their migration are discussed in Section 6.1. No distinctions as to the locations or concentrations of the chemicals detected at or near the site are made in this section. Section 6.2 presents a discussion of contaminant persistence. Potential contaminant migration routes are identified and discussed in Section 6.3. Section 6.4 summarizes fate and transport mechanisms as they pertain to the WOD.

6.1 PHYSICAL AND CHEMICAL TRANSPORT PROPERTIES

This section provides a qualitative discussion of potential migration of the contaminants found at the WOD. The physical and chemical properties of the chemicals found in the study area, where available, are presented in Table 6.1. Partitioning coefficient ranges for detected metals are presented in Table 6.2. These parameters may be used to assess the behavior of a chemical in the environment.

Empirically determined literature values of water solubility, octanol/water partition coefficient (K_{ow}), organic carbon partition coefficient (K_{oc}), soil-water partitioning coefficient, vapor pressure, Henry's Law constant, and specific gravity are presented for organic chemicals, as available. Many of these parameters are not applicable to inorganic chemicals. For inorganics, specific gravity has been presented along with qualitative descriptions of important environmental fate properties. Calculated values, which were obtained using approximation methods, are presented when literature values are unavailable. A discussion of the environmental significance of each of these parameters follows.

6.1.1 Solubility

The rate at which a chemical is leached from a waste deposit by infiltrating precipitation is proportional to its water solubility. Chemicals that are more soluble are expected to enter water much more readily and rapidly than less soluble chemicals. The VOCs (ketones, monocyclic aromatics, and halogenated

aliphatics) are usually several orders of magnitude more water soluble than PAHs and PCBs. At the WOD metals were detected in both soil and groundwater but metals that appeared to be elevated in soils and groundwater did not appear to be collocated, see Figures 5-2 and 5-3. Groundwater samples were collected from shallow monitoring wells that exhibited low yields and relatively high turbidity. Metals detected in these samples may be part of the sediment in the sample instead of the aqueous fraction. This is a manifestation of their limited water solubility and tendency to adsorb onto soil/sediment particles. Filtered groundwater samples were collected to measure the dissolved metals, (see Table 5.4), and although several metals were detected at elevated levels, no single metal was observed in multiple wells and no contaminant pattern is apparent.

The solubility of inorganics is strongly influenced by their valence states and forms (e.g., hydroxides, oxides, carbonates). The solubility is also dependent on pH, Eh, and the presence of other ionic species in solution (the Debye-Huckel theory). Solubility factors reported in the literature vary with the type of complex formed.

In the case of manganese (Mn), which is a common metal and occurs in several natural mineral forms, the predominant species is Mn^{+2} as the solvated (or hydrated) ion at normal pH and ORP values. This ionic state is typically associated with metamorphic rocks. Other manganese compounds, such as permanganate (Mn^{+7}) or manganese oxide (MnO_4), are either too easily reduced to be present in ambient waters or have low solubilities.

6.1.2 Octanol-Water Partitioning Coefficient (K_{ow})

The K_{ow} is a measure of the equilibrium partitioning of a chemical between octanol and water. The K_{ow} is also used to estimate bioconcentration factors (BCFs) in aquatic organisms. A linear relationship between the K_{ow} and the uptake of chemicals by fatty tissues of animal and human receptors has been determined (Lyman et al., 1990). Polycyclic aromatic hydrocarbons (PAHs), phthalate esters, and PCBs are several orders of magnitude more likely to partition to fatty tissues than the more water-soluble VOCs. The K_{ow} is also useful in characterizing the sorption of compounds by organic soils when experimental values are not available. Relatively simple organic chemical molecules have low K_{ow} values.

6.1.3 Organic Carbon Partitioning Coefficient

The soil/sediment partition (organic carbon partition) coefficient (K_{oc}) is related to water solubility and K_{ow}. K_{oc} indicates the tendency of a chemical to bind to soil particles containing organic carbon. Chemicals with high K_{oc} values generally have low water solubilities and vice versa. Chemicals such as semivolatiles, PAHs, and PCBs are relatively immobile in the subsurface environment and are

preferentially bound to the soil phase. These compounds are not subject to groundwater transport to the same extent as compounds with high water solubilities.

K_{oc} may be used to infer the relative rates at which the more mobile chemicals are transported in groundwater. Complex organic chemicals are relatively immobile and are preferentially bound to the soil phase. These compounds are not subject to rapid groundwater transport.

6.1.4 Distribution Coefficient

The soil-water partitioning (distribution) coefficient (K_d) is a measure of the equilibrium distribution of a chemical or ion in soil/water systems. The distribution of organic chemicals is a function of both the K_{oc} and the fractional organic carbon content of the soil (FOC) for the solid and aqueous matrices.

6.1.5 Vapor Pressure

Vapor pressure provides an indication of the rate at which a chemical volatilizes from both soil and water. It is of primary significance in instances where environmental interfaces such as surface soil/air, sediment/air, and surface water/air are important, rather than in evaluation of groundwater and subsurface soils. Vapor pressures for VOCs are generally many times higher than vapor pressures for other organic compounds (e.g., semivolatiles, pesticides, and PCBs). Chemicals with higher vapor pressures are expected to enter the atmosphere much more readily than chemicals with lower vapor pressures. Volatilization depends upon such factors as total exposed surface area, contaminant concentrations, and amount of organic matter in the soil.

6.1.6 Henry's Law Constant

Both vapor pressure and water solubility are of use in determining volatilization rates from surface water bodies and groundwater. The Henry's Law constant (HLC) is the equilibrium vapor pressure of a chemical above a solution divided by its concentration in the solution (for dilute systems). The HLC may also be used to calculate the equilibrium contaminant concentrations in the vapor versus liquid phases for dilute solutions commonly encountered in environmental settings. The HLC is also useful for mass transfer applications for air-stripping column design.

In general, chemicals with a HLC less than E-5 atm-m^3/mole should volatilize very little and be present only in minute amounts in the atmosphere or in soil gas. Chemicals with a HCL greater than 5E-3 atm-m^3/mole, such as halogenated aliphatics and monocyclic aromatics, can undergo significant volatilization and diffusion in soil gas. HLCs (generally measured under laboratory conditions) for some of the PAHs,

semivolatiles, pesticides, and PCBs indicate that these chemicals would tend to volatilize to a limited extent. However, in the environment, these chemicals are strongly sorbed to soil/sediment particles that would keep them from volatilizing into the atmosphere.

6.1.7 Specific Gravity

Specific gravity is the ratio of the weight of a given volume of pure chemical at a specified temperature to the weight of the same volume of water at a given temperature. Its primary use is to determine whether pure compounds or very high concentrations of a contaminant will float or sink in water.

Chemicals with a specific gravity less than 1.0 will tend to float, whereas chemicals with a value greater than 1.0 will tend to sink. Of the commonly detected chemicals at the WOD site, the ketones and monocyclic aromatics have a specific gravity less than 1. Halogenated aliphatics, PAHs, PCBs, phthalate and esters have specific gravity great than 1.

6.2 CONTAMINANT PERSISTENCE

The persistence of the classes of organic and inorganic contaminants found in the study area is discussed in this section. Several transformation processes are believed to affect the persistence of organic chemicals in the environment. The primary processes affecting contaminant fate for organic compounds include microbial, photolytic, chemical degradation (hydrolysis, biodegradation), and oxidation/reduction reactions. For inorganics, persistence may be influenced by soil characteristics such as cation exchange capacity (CEC), TOC, pH, and soil porosity. General classes of the detected chemicals are addressed because the fate of chemicals in the environment is usually similar for chemicals within a particular chemical family.

The following general classes of contaminants are discussed; all of these classes have been detected in samples from the site:

- Monocyclic aromatics
- Halogenated aliphatics
- PAHs
- Phthalate Esters
- Metals
- PCBs

Table 6.3 summarizes those contaminants that were grouped into classes for evaluating persistence. These contaminants include inorganics and organic compounds that were detected at the site (for further details, see Section 5.0.

In general, photolytic degradation is not considered a relevant degradation mechanism for monocyclic aromatic compounds such as toluene (EPA, 1982). Furthermore, even photodegradable compounds must be present in media exposed to sunlight for such degradation to occur (such as surface soil). Because only a few VOCs were detected in surface soil at the WOD, photolytic degradation is not expected.

Generally, organic molecules are subject to several chemical reactions under environmental conditions. Such reaction mechanisms include acid/base reaction, addition, elimination, and hydrolysis. However, monocyclic aromatics are not particularly amenable to the majority of these degradation mechanisms. Hydrolysis is considered negligible for halogenated hydrocarbons. Hydrolysis reactions can occur under acidic, basic, or neutral conditions.

Another possible type of degradation is the dechlorination of tetrachloroethene and trichloroethene to 1,2-DCE, 1,1-DCE, and ultimately vinyl chloride (Cline and Viste, 1984). A similar type of reaction has been reported for 1,1,1-TCA in degradation to 1,2-DCA, 1,1-DCA, and chloroethane. Since only trace levels of some of these compounds (tetrachloroethene, and 1,2-DCE) were detected in the groundwater samples collected at the site, these reactions do not appear to be a major factor in evaluating contaminant persistence/degradation processes at the site under current conditions.

Bacterial degradation is a potential environmental fate mechanism. A compound for which biodegradation is potentially considerable is toluene (EPA, 1982; Verschueren, 1983). This degradation is primarily biological, and anaerobic conditions are typically required for these reactions to occur.

6.2.1 Monocyclic Aromatics

Monocyclic aromatics, such as benzene, toluene, 1,2,4-trimethylbenzene, and xylenes (BTEX compounds), are not considered to be persistent environmental contaminants in comparison to pesticides, PCBs, phthalate esters, and metals. Such compounds are subject to degradation via the action of both soil and aquatic microorganisms. The biodegradation of these compounds in the soil matrix is dependent on several factors including the abundance of microflora, macronutrient availability, soil reaction (pH), temperature, and oxygen. BTEX compounds were detected at the highest levels in subsurface soil and groundwater samples collected from one small discrete area of the site, see Figures 5-2 and 5-3. Other soil and groundwater samples collected surrounding this area did not contain significant levels of BTEX compounds, indicating that the

contaminants may be undergoing some form of degradation or are relatively immobile due to other physical factors.

Although BTEX compounds are amenable to microbial degradation, the rate of degradation cannot be predicted without information on the availability of nutrients and the type of bacteria present. If these contaminants discharge to nearby streams, volatilization and biodegradation may occur relatively rapidly. For example, a reported first-order degradation rate constant for benzene is 0.11 day^{-1} in aquatic systems (Lyman et al., 1990). This corresponds to an aquatic half-life of approximately 6 days.

Additional degradation processes such as hydrolysis and photolysis are considered insignificant fate mechanisms for monocyclic aromatics (EPA, 1982). However, some monocyclic aromatic compounds such as benzene and toluene have been shown to undergo clay-, mineral-, and soil-catalyzed oxidation (Dragun, 1988).

6.2.2 Halogenated Aliphatics

Halogenated aliphatics, such as 1,2-DCE and 1,1,-TCA, are subject to reductive dehalogenation via the action of anaerobic bacteria. Research indicates that degradation of highly chlorinated ethanes is a relatively slow process. It does not appear that appreciable degradation of halogenated aliphatics occurs in aerobic aquatic systems (EPA, 1982) or unsaturated soils (Lyman et al., 1990). Photolysis is not considered to be a relevant degradation mechanism for this class of compounds (EPA, 1982). Limited hydrolysis of saturated aliphatics (i.e., alkanes) may occur, but it does not appear to be a significant degradation mechanism for unsaturated species (i.e., alkenes) (EPA, 1982).

Transport of halogenated aliphatics from groundwater to surface water can occur. When discharged to surface water, these compounds tend to volatilize rapidly due to their high solubility rather than bind with sediments.

6.2.3 PAHs

PAHs are common constituents of oil and grease and may be present at the site due to reported disposal of these types of materials at the site. Data from landspreading applications have indicated that PAHs are amenable to microbial degradation. Studies have demonstrated that PAHs are much more amenable to degradation in soil matrices than in aquatic environments (EPA, 1979). Under existing site conditions, the rate of microbial degradation cannot be predicted without knowledge of microbial populations. PAHs do not contain functional groups that are susceptible to hydrolytic actions, and hydrolysis is considered to

be an insignificant degradation mechanism. Photolysis may be a major degradation mechanism in aquatic environments but is probably insignificant in solid materials.

6.2.4 Phthalate Esters

Phthalate esters are considered to be relatively persistent environmental contaminants. Although numerous studies have demonstrated that phthalate esters undergo biodegradation, it appears that this is a very slow process in both soil and surface water. Certain microorganisms have been shown to excrete products that increase the solubility of phthalate esters and enhance their biodegradation (Gibbons and Alexander, 1989). Biodegradation of bis(2-ethylhexyl) phthalate and other phthalate esters is an important fate mechanism, as is bioaccumulation. Hydrolysis of phthalate esters is very slow, with calculated half-lives of 3 years (dimethyl phthalate) to 2,000 years [bis(2-ethylhexyl) phthalate] (EPA, 1979). Similarly, photolysis is considered to be an insignificant degradation mechanism for phthalate esters (EPA, 1982).

6.2.5 PCBs

PCBs are considered to be very persistent organic chemicals. Biodegradation is the only process known to transform PCBs under environmental conditions, and only the lighter compounds are measurably biodegraded (EPA, 1979). Although some microorganisms may biodegrade PCBs, such fungi may not exist in local soil. There is experimental evidence to suggest that heavier PCBs (five or more chlorines per molecule) can undergo photolytic degradation, but there are no data to suggest that this process operates under environmental conditions (EPA, 1979). Base-, acid-, and neutral-promoted hydrolysis are considered inconsequential degradation mechanisms for PCBs (EPA, 1982).

6.2.6 Metals

The transport and fate of metals in the environment are primarily controlled by sorption to soil/sediment material. Some key parameters affecting mobility of metals in groundwater are listed in Table 6.2. The metal-organic relationships, both in soil and water, increase in importance as the organic carbon content increases. Some metals (e.g., arsenic) are extremely soluble and mobile in the environment. Many other metals, such as zinc and copper, have an affinity for hydrous iron and manganese oxides, as well as for organic materials, and are therefore preferentially adsorbed to soil. The mobility of most metals increases as the soil pH decreases. Table 6-3 presents the metals of concern for the various media.

Inorganic contaminants with a positive charge (cations) will be retarded by clays exhibiting a net negative charge, and anions such as chromium (as chromate) and arsenic (as arsenate) will be more mobile in such

an environment. The mobility of metals in soil is also influenced by the metals' ability to form insoluble precipitates, bind to metal oxides in the soil, or remain insoluble.

6.2.7 Summary

A summary of the fate processes for each of the critical compounds found in the study area is shown in Table 6.4. This table helps identify which compounds would be the most persistent in the environment. Metals and PAHs are the most persistent compounds found that may be attributable to the site. The metals detected do not undergo volatilization, biodegradation, or photolysis as fate processes.

6.3 CONTAMINANT MIGRATION FACTORS AND ROUTES

In general, several potential migration routes exist in areas contaminated with hazardous materials. For the WOD, such migration routes include, but are not limited to,

- Atmospheric migration via particulate or volatile vaporization or fugitive dust emissions from the site.
- Overland migration of dissolved or adsorbed contaminants.
- Leaching from the site soils to underlying groundwater.
- Groundwater transport to surface water.

Contaminants migrating from the site may be transported through one or more environmental media. The physical and chemical characteristics of those media affect the interactions between the contaminant and the media and determine how, or if, a given contaminant migrates in a particular medium. The environmental media identified in Section 5.0 as being potentially contaminated by site activities include surface and subsurface soil and groundwater.

The environmental factors that have the greatest influence over the mobility of contaminants in the various media include

- Hydraulic conductivity
- Cation exchange capacity (CEC)
- Organic carbon content
- Hydraulic gradient
- pH
- oxidation/reduction potential (ORP)
- Groundwater/surface-water interactions
- Dissolved oxygen

- Temperature
- Specific conductance

6.3.1 Atmospheric Migration

The first possible route for contaminant migration from the site through the air is the volatilization of compounds from surface water or surface and subsurface soil (especially if exposed through excavation or erosion). The results of the sampling and analysis indicate that this is not happening on a significant scale on a site-wide basis. VOCs were infrequently detected and at low (near quantitation limit) levels in surface soils, see Table 5.7 and Figure 5-1.

The second possible route for contaminant migration from the site through the air is the generation of contaminant dusts from surface soil. This would be potentially important for metals and possibly for organic chemicals strongly sorbed to soil particles. Subsurface soil fugitive dust exposure would depend upon the subsurface material being exposed in some way. Potential future risks associated with estimated dust emissions via inhalation of suspended particles from soils are assessed in Section 7.0.

6.3.2 Soil Migration

Surface soils may be transported by water erosion during rainstorms and other precipitation events. Along with overland flow of contaminants, wind erosion may be responsible for the movement of fine-grained particles on site. The soil properties that affect permeability or potential reaction with the dissolved components in the water include not only permeability and hydraulic conductivity but also CEC, mineral content of the soil, and the soil organic carbon content. Overburden materials present at the site are predominantly silty or loamy sands.

Samples from the WOD indicate that substantial levels of organic contamination of surface soils are not wide-spread at the site. As depicted in Figure 5-1, low levels of PAHs were primarily detected within a small surface stain that appeared to be highly weathered petroleum product. Most metals are present but at levels similar to background levels. However, silver was detected at levels that appear to be above background concentrations, especially in surface soil samples collected at the base of the bank along the unnamed tributary to Little Mosquito Creek and in a subsurface sample collected from fill material encountered in this area of the site, see Figures 5-1 and 5-2. The migration of contaminants through the soil partly depends on the capacity for fluid movement through the subsurface. Hydraulic conductivity is a measure of the rate at which water flows through the soil or rock under a change in pressure, or head. Soils generally classified as loamy sands are considered well-drained.

The fate of metals in surface soils may be largely controlled by weathering and the absorptive capacity of the soil. Absorption will control the amount of metals that can be retained within the soil. The capacity of soil to immobilize ionic inorganics can be reasonably predicted based on a correlation equation involving pH and CEC. CEC is a measure of the capacity of the soil to adsorb positively charged ions such as metals onto the negatively charged surface of the soil particles. Although soils were not analyzed for CEC during the WOD investigations, it is likely that they would exhibit high CEC values and would have a generally high capacity to adsorb metals.

Generally, a soil composed of clay or a clay mixture attenuates (slows) dissolved ions during transport more than does a clay-free soil. Conversely, a soil composed of well-sorted (i.e., clay-free) quartz sand and gravel typically has little or no capacity to adsorb or exchange an ionic substance (e.g., metals or radionuclides) migrating through it. Therefore, soils present at the site are not expected to significantly attenuate contaminants via this mechanism as they consist of well-drained loamy sands. The soils surrounding the site, marsh soils, were noted to be of a higher organic and silt content and would likely adsorb or attenuate metals.

The amount of organic carbon present in a soil also increases the relative amount of an organic compound that will be attenuated by that soil. In effect, the organic carbon content increases the effective distribution coefficient (K_d) of chemical species in solution. The greater the organic carbon content in the soil, the more likely it is that organic compounds migrating through the soil will become adsorbed onto the soil and the less likely they will migrate long distances through it. If appropriate pathways exist, contaminants retained on soils or sediments could migrate off site with surface water flowing away from the site. The Supplemental RI surface soil samples were analyzed for TOC and the samples collected from the marsh area around the site, (samples WOD-SS-128 through WOD-SS139) in general, exhibited higher TOC levels than the samples collected from the site itself, see Table 5.1. The samples collected along the unnamed tributary to Little Mosquito Creek exhibited the highest TOC levels.

The soil pH factor helps predict the mobility of inorganic species and is defined as a measure of the hydrogen ion concentration. The soil pH is important with respect to a metal's ability to remain soluble or to precipitate as a particular salt. Several metals, including lead, are soluble at both basic and acid pH conditions. These metals are considered amphoteric. The soil at the WOD is classified as acidic in nature and Supplemental RI soil samples had a pH range from 4.3 to 7.1.

6.3.3 Groundwater Migration

Migration and transport of contaminants in groundwater are a potential release mechanisms at the site. Both organic and inorganic contaminants from the surface and subsurface soils can enter the groundwater and be transported vertically and horizontally. The WOD groundwater flow patterns are

detailed in Section 4.5. Groundwater vertical gradients are generally in a downward direction and groundwater flow is influenced by the site topography. The site is bisected by a groundwater divide and groundwater flows in a northeasterly and northwesterly direction toward Little Mosquito Creek and its tributaries and associated wetlands. Little Mosquito Creek, located to the north of the WOD, is expected to be the regional groundwater discharge zone.

The groundwater analytical data from the site revealed the presence of VOCs, primarily BTEX compounds. The presence of these contaminants is limited, in the most part, to one well, see Figure 5-3. This well also contained a free product layer before development. The product layer did not return after a two week period, see Section 4.4, and contaminant levels detected in the sample from this well are not indicative of the presence of free product (see Figure 5-3).

Advective transport and mechanical dispersion in groundwater are the principal mechanisms by which VOCs and other contaminants are transported away from the site. The first and most likely route of contaminant migration is through surface soil to subsurface soil, where contaminants enter the upper flow zone. As water infiltrates through a contaminated zone, partitioning from solid to aqueous phase will occur. The potential amount of chemical dissolving into infiltrating water is determined by a number of factors, including residence time, solubility, partitioning factor, and pH of the water. The dissolved chemicals continue downward and are able to interact with stationary (soil) particles in the saturated and unsaturated zones. After percolating through the capillary zone, dissolved contaminants are then able to enter groundwater, where transport can occur in bulk through advection. The chemical concentrations in groundwater increase significantly shortly after initial groundwater impact to a maximum level. The longer-term effects at the source are a gradual decrease in the concentrations over time as chemical removal from the source area occurs. Short-term variations in release rate and impact to groundwater can occur, but long-term trends of decreased levels are usually observed. Diffusion and dispersion throughout the groundwater flow regime occur as the groundwater flows.

During groundwater contaminant transport, a number of processes help to reduce chemical concentrations. Diffusion and attenuation effects are non-transformational mechanisms that result in a direct decrease in chemical concentrations. Chemical and biological reactions with dissolved chemicals can also result in decreased concentrations. The products, however, may have significantly different chemical, transport, and toxicological properties from the parent compounds.

Sampling results from the WOD monitoring wells indicate that groundwater contaminants are isolated to one discrete area and are not migrating at detectable levels, see Section 5.4.3.

6.4 SITE-SPECIFIC ENVIRONMENTAL FATE OF CONTAMINANTS OF POTENTIAL CONCERN

This section identifies the potential contaminant release and transport mechanisms identified through evaluation of the chemical analytical data and known characteristics of the site. This section will also address existing and potential migration routes at the site, in particular migration through surface and subsurface soil and groundwater.

Three basic factors influence the potential migration of contaminants:

- Physical and chemical properties of the specific compounds;
- Physical and chemical characteristics at the site and in the surrounding study area; and
- Volume and concentration of contaminants.

6.4.1 Surface and Subsurface Soil

As evidenced by the analytical data, various organic compounds including monocyclic aromatics, halogenated aliphatics, PAHs, and VOCs were detected at generally low levels in surface and in slightly higher levels in subsurface soil at the site. The frequency of detection was also low and confined to a small area of surface staining at the site. The highest number and level of metals were detected in a subsurface sample collected from waste materials encountered in the west-central portion of the site.

The VOCs detected at the site are highly mobile in soil environments. The VOCs would tend to move downward into the groundwater column. The other organics and metals detected in the WOD soils are generally highly sorbed onto soil particles and generally are immobile in the environment. Site data indicates that VOCs are present at the highest concentrations and frequency in the subsurface area immediately below the surface stain and that the levels are relatively low. The contaminant pattern present in these soils, primarily ethyl benzene, toluene and xylenes, is similar to the contaminant pattern seen in groundwater samples collected in the same area, indicating that the subsurface soils may be associated with the source of the groundwater contamination. However, the level of contaminants present in the subsurface soils, see Section 5, is considered relatively low in comparison to the groundwater levels. In addition, the contaminant concentrations detected in the subsurface soils and groundwater are below the EPA soil screening guidance for the soil to groundwater pathway. The contaminant levels detected in WOD soils were qualitatively reviewed to evaluate the soil to groundwater pathway. Table 6.5 presents the results of this evaluation. The EPA screening criteria is shown for those contaminants that were found in groundwater and were detected in site soils and which, for metals, were present at levels greater than background. For each substance, maximum concentrations found in soils were compared to their respective soil screening level (SSL) (EPA, 1996d). EPA's on-line SSL calculator was used to define the SSL. Assumptions used in this process are

presented in Table 6.5 and in Appendix G. No groundwater contaminant was detected in site soils (and at levels that exceed background for metals) and the screening criteria.

The site data suggests that WOD soils are not currently a significant source of contaminant release to the environment. Past removal actions and/or of years of exposure to infiltration of precipitation and groundwater flushing may have removed the majority of soluble contaminants from the soils. It is also possible that the source was introduced at the water table through excavation and disposal, see Section 5.5.

6.4.2 Groundwater

As evidenced by analytical data, the major groundwater contaminants detected at the site were volatile organics, primarily monocyclic aromatics, and metals. Based on the available data and site records, it is believed that the VOC compounds were introduced at the WOD through diposal activities and appear to have remained in the groundwater at the point of disposal. The dissolved waste components do not appear to have migrated beyond the point of disposal and contamination is limited to a small discreet portion of the site. Section 5.4.3 presents a detailed evaluation of the nature and extent of contamination in groundwater and Section 5.5 presents a detailed conceptual model for the WOD. Supplemental RI and historical data indicate that contamination within the groundwater is not migrating at detectable levels from the site and the contaminant levels appear to be at steady state or slightly decreasing in magnitude.

Metals contamination in groundwater samples collected from the WOD do not indicate a contaminant pattern that is consistent with past operations or current soil contaminant levels. Chromium was detected at elevated concentrations in samples collected from two monitoring wells (WFF16-GW1 and -GW3) but was detected at elevated levels in only one soil sample (WOD-SU-111-0507) collected from a different part of the site located on the opposite side of the groundwater divide that bisects the site, see Figure 4-4. Similarly, the only well sample that contained arsenic (WFF16-GW2D) is located upgradient of the only soil sample (WOD-SU-111-0507) that contained elevated arsenic levels, see Figure 4-4. The sample from this well also exhibited a low ORP (-51 mv) and dissolved oxygen content (0.49 mg/L) which may be indicative of a reducing environment which may enhance dissolution of metals from native materials.

7.0 HUMAN HEALTH RISK ASSESSMENT

This section provides a description of the risk assessment methods employed for the supplemental soil and groundwater risk assessment for the NASA WFF Waste Oil Dump Site (WOD), as well as a summary of the soil and groundwater risk assessment results. The general objectives of the risk assessment were to estimate the actual or potential risks to human health resulting from the presence of contamination in area groundwater, surface soil, and disturbed soil (footnoted as soil* to denote surface and subsurface soils that have been mixed), and to provide the basis for determining appropriate remedial measures (if necessary) for these media as part of the Feasibility Study.

7.1 INTRODUCTION

The specific objectives of the risk assessment were as follows:

- To estimate the actual or potential risks to human health resulting from the presence of contamination in area groundwater, surface soil, and soil* (mixture of surface and subsurface soils), at designated areas/media of concern.

- To provide a basis for establishing concentrations that are protective of potential human receptors under industrial, construction, and residential exposure scenarios.

- To determine the need for remedial measures (if applicable) for these media.

Three major aspects of chemical contamination must be considered when assessing public health risks: (1) contaminants with toxic characteristics must be found in environmental media and must be released by either natural processes or by human action; (2) potential exposure points must exist either at the source or via migration pathways if exposure occurs at a remote location other than the source; and (3) human or environmental receptors must be present at the point of exposure. Risk is a function of both toxicity and exposure; without any one of the three factors listed above, there is no risk.

This risk assessment is divided into Data Evaluation, Estimation of Exposure Point Concentrations, Exposure Assessment, Toxicity Assessment, Risk Characterization, Uncertainty Analysis, and Summary/Conclusions. Each section is briefly discussed below. Note that the tables associated with this section follow a standardized format adopted by EPA Risk Assessment Guidance for Superfund (RAGS), Volume I, Part D: Standardized Planning, Reporting, and Review of Superfund Risk Assessments.

Several aspects of Data Evaluation (Section 7.2) are primarily concerned with analytical data treatment methodology and were discussed in the preceding section, including handling of qualifiers and nondetects, averaging of duplicates, distributional analysis of the data, and background comparison tests. Once these steps are complete, chemicals of potential concern (COPCs) are selected for each medium that represent the potential contributors to significant site-associated risks. COPCs for each medium of interest are summarized on RAGS D Table 2s.

Estimation of Exposure Point Concentrations (Section 7.3) provides a statistical procedure for estimating the chemical input into each of the exposure pathways. The shape of the data distribution and magnitude of the standard deviation for each COPC define the basis for calculating the upper 95 percent confidence limit on the mean concentration, which is the input concentration of a chemical used to estimate the site-associated risks. Different methods of calculating EPCs apply for lead. EPCs are presented for each medium of interest on RAGS D Table 3s.

Exposure Assessment (Section 7.4) identifies categories of potential human health exposure based upon a characterization of the site setting, delineates potential receptors consistent with current and possible future land use patterns, outlines possible exposure routes by medium, documents the parameters and equations used in exposure estimates for each pathway, and explains the exposure evaluation used in blood-lead modeling. Exposure input parameters for each receptor and exposure pathway are presented on RAGS D Table 4s.

Toxicity Assessment (Section 7.5) presents available reference doses, cancer slope factors, EPA weight of evidence, adjustment of the dose-response parameters, chemical-specific dermal absorption factors, and toxicity equivalency factors (TEFs) for dioxins/furans. In this section, toxicity factors for noncancer toxicity and cancer risks are presented for all COPCs on RAGS D Table 5s and 6s, respectively.

Risk Characterization (Section 7.6) presents the approaches for determining carcinogenic risks, noncarcinogenic risks, and lead risks. The risk characterization quantitatively evaluates the potential for adverse health effects from exposure to COPC concentrations in environmental media by integrating information developed during the toxicity and exposure assessments. In this section, RAGS D Table 9s present noncancer risks subdivided according to target organ and a total of cancer and noncancer risks summed across all COPCs for each environmental medium, exposure pathway, and receptor. An overall cumulative summary of risks across all media and pathways of exposure is also presented for each receptor.

Uncertainty Analysis (Section 7.7) is a discussion of the general and site-specific uncertainties associated with the estimated risks, exposure models, and assumptions utilized in the HHRA.

7.2 DATA EVALUATION

7.2.1 Identification of COPCs

The selection of COPCs was based on chemical-specific concentrations, occurrence, distribution, and toxicity. Groundwater, surface soil, and subsurface soil analytical data were used to select COPCs by examining only those chemicals with positive detections. Groundwater and surface soil data were evaluated as separate media to which receptors might be exposed, whereas data from surface and subsurface soils were combined to allow evaluation as a single exposure medium (denoted as soil*) that represents potentially disturbed soil for future potential receptors. All site-related subsurface soil samples were evaluated in Sections 5 and 6 for the purpose of evaluating the overall extent of contamination and for soil-to-groundwater pathway screening. However, subsurface soil samples collected from depths below 15 feet are not considered available for potential exposure and are not relevant to the human health risk assessment. While future site activities may result in mixing and redistribution of subsurface soils, the EPA guidance generally limits the potential exposure depth to 10 feet and VADEQ guidance limits the depth of consideration to 15 feet or to groundwater, whichever is encountered first. Five WOD subsurface soil samples were collected from depths greater than 15 feet. For human health risk assessment purposes, these samples were omitted from the data.

A substance was considered a candidate COPC for an exposure medium if the maximum detected concentration was greater than the associated risk-based concentration (RBC) based on a target cancer risk of 1×10^{-6} or a noncancer hazard quotient (HQ) of 0.1. RBCs were obtained from the latest EPA Region 3 Risk Based Concentrations (RBCs) listing for soil and tap water (EPA, 2003a). All exposures to groundwater, surface soil, or soil* for all receptors were conservatively screened using the residential exposure assumptions in the RBC table. RBCs that were based on noncancer effects were adjusted from a HQ of 1.0 to a HQ of 0.1 to protect against the possibility of additive toxic effects from multiple chemicals.

For soil media, candidate COPC metals were eliminated from quantitative risk calculations if none of the statistical tests indicated that levels were greater than background. [Such metals might contribute to background risks but not to site-related risks and are discussed further in the Uncertainty Analysis (Section 7.7).] The statistical methodology for comparing site data to background was presented in section 5.3. Results of background comparisons for surface soil are discussed in Section 5.3.4 and are presented in Table 5.5. For subsurface soil, relevant background comparison test results are presented in Appendix G. (Note that the table of background comparison results shown in Appendix G is considered relevant only to the direct contact exposure evaluation for the human health risk assessment because it omits soil samples collected at depths below 15 feet, while five additional samples from depths

below 15 feet were added to the data set used for the purpose of evaluating the overall site-related extent of contamination and for soil-to-groundwater pathway screening in Section 5.)

For surface soil, metals that exceeded RBCs were appropriately considered as COPCs for quantitative risk calculations if the outcome of any quantitative statistical test was above background (Y) or if all background tests were considered as not applicable (NA) because of diminished or unreliable capacity to detect a significant difference between site and background. (This can occur, for example, if there are very few samples, too many nondetected results, or other problems with the data.) For the evaluation of candidate COPC metals in soil* (mixture of surface and subsurface soil) two separate series of background tests - one for surface soil and one for subsurface soil - were considered in conjunction. Candidate COPC metals in soil* were eliminated from the risk assessment based upon background tests if at least one of the two data sets (either surface or subsurface soil) was qualified as not above background (N) and neither data set was judged to be above background (Y) for a particular COPC.

COPCs for metals present in groundwater were selected based only upon RBC comparisons and in lieu of any statistical background comparisons. Background tests were not considered reliable for groundwater because of a statistically inadequate number of site-specific upgradient sample locations (data were collected only for two upgradient wells). However, a qualitative comparison of site and background samples for groundwater is presented within the Nature and Extent of Contamination (Section 5).

Other considerations were applied to evaluate whether chemicals that do not have published RBC criteria should be selected as COPCs. Essential nutrients were not considered as COPCs, including calcium, chloride, magnesium, potassium, and sodium. Where possible, detected chemicals that did not have published toxicity criteria were compared to surrogate RBC criteria that were adopted from available RBCs for substances having similar chemical structure. The RBC for pyrene was used as a surrogate for evaluating phenanthrene and benzo(g,h,i)perylene since the latter substances do not have published RBCs. Other detected chemicals that did not have published toxicity criteria from accepted references (EPA, IRIS, HEAST, or NCEA) were not retained as COPCs but are addressed in the Uncertainty Analysis (Section 7.7) to document cases where a current lack of knowledge regarding toxicity adds uncertainty to the risk assessment.

A lead value of 400 mg/kg [Office of Solid Waste and Emergency Response (OSWER) Directive, EPA, 1994a] was used as the residential soil screening RBC level and was applied to surface soil and soil* (mixture of surface and subsurface soils). Lead was evaluated as a potential COPC in groundwater based upon comparison to the action level of 15 ug/L.

The RBC for hexavalent chromium was used for COPC selection because speciation data (i.e., trivalent versus hexavalent) were not available for samples collected at WOD. Similarly, the RBC for methyl mercury was used for COPC selection because the form of mercury at the site is unknown and methyl mercury is considered the most toxic form of mercury.

Results of selection of COPCs for each of the media of concern at WOD are presented in the following subsections. The COPC selections and the rationale for inclusion or exclusion of chemicals are presented in Tables 7.1 through 7.3. Chemicals with a "Y" listed in the COPC selection column of each table were retained as COPCs for all quantitative risk calculations.

7.2.1.1 Surface Soil COPC Selection

The following substances were selected as COPCs in surface soil and are shown on Table 7.1:

- Benzo(a)pyrene

While the above PAH exhibited maximum concentrations above screening criteria, nine additional PAHs were detected at levels below RBCs and therefore are not expected to contribute to significant site-related risks. Seventeen VOCs were detected at concentrations less than RBCs. Maximum concentrations of the metals aluminum, arsenic, iron, manganese, and vanadium exceeded their respective RBCs but all of these metals were found to be not above background based upon statistical tests shown in Table 5.5.

While COPC selection was contingent upon maximum detected concentrations exceeding RBCs, from a risk-based perspective it is significant to note other descriptive statistics to better understand the range of detected concentrations that may affect risk for specific COPCs. For example, the benzo(a)pyrene arithmetic mean also exceeded the respective screening RBC. Benzo(a)pyrene was detected in nine out of 60 samples at concentrations ranging from 47 ug/kg to 1300 ug/kg.

7.2.1.2 Soil* COPC Selection

The following substances were selected as COPCs in soil* (mixture of surface and subsurface soil) and are shown on Table 7.2:

- Antimony
- Silver
- Benzo(a)pyrene

While the above PAH exhibited a maximum concentration above the screening criteria, 9 additional PAHs were detected at levels below RBCs and therefore are not expected to contribute to significant site-related risks. 18 VOCs were detected at concentrations less than RBCs and at low frequencies of detection (most VOCs were detected in less than 10 percent of samples, with the only exceptions being acetone, 2-butanone, and methyl acetate). Maximum concentrations of the metals aluminum, arsenic, barium, cadmium, chromium, copper, iron, lead, manganese, thallium, vanadium, and zinc exceeded their respective RBCs but all of these metals were found to be not above background in surface soil and subsurface soil based upon statistical tests shown in Tables 5.5 and 5.6.

While COPC selection was contingent upon maximum detected concentrations exceeding RBCs, from a risk-based perspective it is significant to note other descriptive statistics to better understand the range of detected concentrations that may affect risk for specific COPCs. For example, benzo(a)pyrene arithmetic mean also exceeded the respective screening RBC. Benzo(a)pyrene concentrations ranged from 47 ug/kg to 1300 ug/kg.

The maximum detected concentrations of antimony and silver exceeded their respective screening RBCs. In contrast, the arithmetic means for these COPCs were each less than their respective screening RBCs, indicating that average exposure concentrations would be below screening criteria. Antimony was detected in 3 out of 59 samples at concentrations ranging from 0.36 to 18.3 mg/kg. Silver was detected in 37 out of 72 samples at concentrations ranging from 0.11 to 389 mg/kg.

7.2.1.3 Groundwater COPC Selection

The following substances were selected as COPCs in groundwater and are shown on Table 7.3:

- Aluminum
- Arsenic
- Chromium
- Iron
- Lead
- Manganese
- 2-Methylnaphthalene
- 4-Methylphenol
- Bis(2-ethylhexyl) Phthalate
- Dibenzofuran
- Naphthalene
- 1,2,4-Trimethylbenzene

- 1,3,5-Trimethylbenzene
- Benzene
- Tetrachloroethene
- Toluene
- Xylene (Total)

The 6 VOCs listed above exhibited maximum concentrations above screening criteria. Six additional VOCs were detected at levels below RBCs and therefore are not expected to contribute to significant site-related risks. Individual xylene isomers exceeded RBCs as well as total xylenes. Note that screening criteria and toxicity factors are identical for all xylene isomers so risk characterization can be performed without loss of specificity using only the sum of isomers, xylene (total), rather than individual isomers. This approach is more representative because it accounts for the cumulative exposure at each sample location.

Six metals exceeded RBCs and nine metals were below RBCs. Background tests were considered not applicable for groundwater due to a limited number of samples so COPC selection was based only on RBC comparison. The locations of maximum detected concentrations of organics in subsurface soil (samples 2WFF16-SB2S2 and 2WFF16-SB1S2) represent the two samples nearest the monitoring well location (WFF15-GW7) where the groundwater concentrations of BTEX, naphthalene, manganese, and lead were maximum, and arsenic and iron levels in the top 3 ranked concentrations among WOD groundwater samples. This coincidence might suggest localized site-related influence on metals in groundwater at this location, but a hot spot source of these metals in soil is not indicated because these metals were not found at levels statistically greater than background in subsurface soil and arsenic and iron levels in groundwater were higher at locations removed from the vicinity of the location of BTEX groundwater detections. Note that arsenic, chromium, and lead were not detected in upgradient samples and upgradient levels of manganese and iron were several orders of magnitude less than the maximum levels found downgradient or within the WOD site.

While COPC selection was contingent upon maximum detected concentrations exceeding RBCs, from a risk-based perspective it is significant to note other descriptive statistics to better understand the range of detected concentrations that may affect risk for specific COPCs. For several chemicals, the arithmetic mean of groundwater concentrations exceeded the respective screening RBC; this was the case for arsenic, chromium, iron, manganese, 2-methylnaphthalene, dibenzofuran, naphthalene, benzene, and tetrachloroethene. Arsenic was detected in one out of eight samples at a concentration of 21.4 µg/L and chromium was found in three groundwater samples at concentrations ranging from 6.1 to 147 µg/L. Iron was detected in all 12 groundwater samples at concentrations ranging from 50.6 to 49900 µg/L. Manganese was detected in all 12 groundwater samples at concentrations ranging from 15 to 641 µg/L. Dibenzofuran,

2-methylnaphthalene, naphthalene, 1,2,4-Trimethylbenzene, 1,3,5-trimethylbenzene, tetrachloroethene, and xylene (total) were detected in one out of 12 samples at concentrations of 4 µg/L, 130 µg/L, 130 µg/L, 170 µg/L, and 74 µg/L, 5 µg/L, and 540 µg/L, respectively. Benzene was detected in two out of 12 samples at concentrations ranging from 8 to 11 µg/L.

The maximum concentrations of aluminum, lead, 4-methylphenol, bis(2-ethylhexyl)phthalate, and toluene exceeded their respective screening RBCs. Note that the arithmetic means were less than their respective screening RBCs, indicating that average exposure concentrations would be below screening criteria. Aluminum was detected in five groundwater samples at concentrations ranging from 831 to 8220 µg/L. Lead was detected in two out of 12 samples with concentrations ranging from 5.1 to 68.6 µg/L. 4-Methylphenol was detected in one out of 11 samples at a concentration of 42 µg/L. Bis(2-ethylhexyl)phthalate was detected in three out of 12 samples at concentrations ranging from 2 to 18 µg/L. Toluene was detected in two out of 12 samples at concentrations of 2 and 120 µg/L.

7.3 EXPOSURE POINT CONCENTRATIONS

In this risk assessment, an exposure point concentration (EPC) represents an estimated chemical concentration to which a receptor is assumed to be continuously exposed while in contact with an environmental medium. Using all the analytical results for related samples, an EPC was calculated for each COPC identified in each medium of concern at the WOD Site. The EPC was calculated using the latest risk assessment guidance from EPA (1989a, 1991a, 1991b, 2000, 2002a, 2002b), Gilbert (1987), and Singh (1999). The shape of the data distribution and magnitude of the standard deviation for each COPC define the basis for calculating the upper 95 percent confidence limit on the mean concentration, which is the input concentration of a chemical used to estimate the site-associated risks.

Before EPCs are calculated, the analytical database is manipulated to remove unusable data points, average field duplicate results, and calculate statistics that determine the potential distributional shape of the data as previously discussed in Section 5.3.2, Data Pretreatment. The results of calculations of the shape of the data distribution are presented in distributional analysis tables in Appendix G. This information, together with the calculated magnitude of the standard deviation or standard deviation of log-transformed data for each COPC, defines the basis for calculating the upper 95 percent confidence limit on the mean concentration, which is the input concentration of a chemical used to estimate the site-associated risks.

7.3.1 Reasonable Maximum and Central Tendency Exposure EPCs

Two types of EPCs are possible for use in this risk assessment, reasonable maximum exposure (RME) EPCs and central tendency exposure (CTE) EPCs. RME is the exposure that is expected to represent a high end, but not worst-case, exposure in a given medium of concern. CTE is the exposure that is expected to represent an average exposure to receptors in a given medium of concern. The CTE EPC was selected to be the same as the RME EPC, in accordance with EPA Region 3 recommendations. Therefore, in this risk assessment, CTE analysis involves changes only to the input parameters for each exposure pathway and not the EPC. (Note: CTE analysis at WOD was performed only for those exposure pathways where the estimated cancer risks are above 1×10^{-4} and the non-cancer HIs based on the same target organ are above 1.0.)

7.3.2 EPC Calculations

EPCs are selected following a decision scheme that chooses from several options, depending upon how many data points exist, whether the data are normal or lognormally distributed, and the particular value for the standard deviation of logarithmically-transformed chemical concentrations. EPCs can be either the maximum value, 95 percent upper confidence limit on the mean of normally distributed data (95 percent UCL-N), the 95 percent H-statistic upper confidence limit on log transformed data (95 percent UCL-H), the Chebychev 95 percent confidence limit on logarithmically-transformed data using minimum variance unbiased estimates (95 percent UCL-Cheby-mv), the Chebychev 99 percent confidence limit on log transformed data using minimum variance unbiased estimates (99 percent UCL-Cheby-mv), the Chebychev 95 percent confidence limit assuming a nonparametric distribution (95 percent UCL-Cheby), the Chebychev 97.5 percent confidence limit assuming a nonparametric distribution (97.5 percent UCL-Cheby), or the Chebychev 99 percent confidence limit assuming a nonparametric distribution (99 percent UCL-Cheby). All the foregoing represent conservative estimates of the mean, each of which is appropriate under different circumstances.

EPCs for lead were calculated differently because the model is designed to accept the mean lead value and estimate the upper percentile of blood-lead concentrations from this quantity. Therefore, in the case of lead, the candidate RME EPC was selected as the arithmetic mean of the lead concentration (for a normal distribution) in every case.

The calculation of an EPC involves two steps. First, the distribution of the data was evaluated as described in the preceding section. Then, based on the distribution of the data, an EPC was either calculated or selected.

Several important assumptions were used to evaluate the distribution of the data (Section 5.3.2):

- The distribution of a data set was classified as lognormal, normal, or unknown (i.e., nonparametric) using the results of the Shapiro Wilk W-test. If the W test accepted the hypothesis of a normal distribution, then the W test using the logarithmic conversion was not applicable and the estimation of the upper 95th percentile confidence limit on the mean was based upon a normal distribution and standard deviation. If the normal distribution did not pass the W-test, then the W-test was evaluated for a logarithmic transformation of data. If the data were neither normal nor lognormally distributed, but the standard deviation of the logarithms was less than 0.5, a normal distribution was assumed. Otherwise, if neither distribution matched the data set of interest, a nonparametric distribution was assumed.

- If fewer than three samples were available in the area or medium of concern, estimation of the distributional shape was not possible and the 95 percent UCL was not estimated.

- If fewer than five samples were available, the determination of distributional shape and the estimation of statistical upper confidence limits were not considered reliable or accurate because of inadequate sample size, and the maximum value was selected as the EPC in this case.

If the data were determined to be normally distributed, then the standard deviation of the sample set and the student's t-value were used to calculate the one-sided 95 percent UCL, as follows:

First, the standard deviation of the sample set was determined:

$$S = \sqrt{\sum\left(\frac{(X_i - m)^2}{n-1}\right)}$$

where:

S	=	Standard deviation of the data
X_i	=	Individual sample value
μ	=	Arithmetic mean of the n samples
n	=	Number of samples

The one-sided upper 95 percent confidence limit (95 percent UCL-N) was calculated as follows:

$$95\%UCL - N = m + \frac{(t \times S)}{\sqrt{n}}$$

where:

S	=	Standard deviation of the data
t	=	One-sided t distribution factor
μ	=	Arithmetic mean of the n samples
n	=	Number of samples

If the data were considered to be lognormally distributed, then the EPC was selected following a decision scheme listed below. The EPC was based on either the maximum value, the 95 percent H-statistic upper confidence limit on log transformed data (95 percent UCL-H), the Chebychev 95 percent confidence limit on log transformed data using minimum variance unbiased estimates (95 percent UCL-Cheby-mv), the Chebychev 99 percent confidence limit on log transformed data using minimum variance unbiased estimates (99 percent UCL-Cheby-mv), the Chebychev 95 percent confidence limit (95 percent UCL-Cheby), or the Chebychev 99 percent confidence limit (99 percent UCL-Cheby). The following table presents the type of upper confidence limit chosen according to the number of data points and the observed value for the log standard deviation:

Statistical UCL Methods for Lognormally Distributed Data

No. of Data Points	Log Standard Deviation	Type of UCL
N < 5	--	Maximum value
N ≥ 5	0.5 ≤ S < 1.0	95% UCL-H
5 ≤ N < 25	1.0 ≤ S < 1.5	95% UCL-Cheby-mv
N ≥ 25	1.0 ≤ S < 1.5	95% UCL-H
5 ≤ N < 20	1.5 ≤ S < 2.0	99% UCL-Cheby-mv
20 ≤ N < 50	1.5 ≤ S < 2.0	95% UCL-Cheby-mv
N ≥ 50	1.5 ≤ S < 2.0	95% UCL-H
5 ≤ N < 25	2.0 ≤ S < 2.5	99% UCL-Cheby-mv
25 ≤ N < 70	2.0 ≤ S < 2.5	95% UCL-Cheby-mv
N ≥ 70	2.0 ≤ S < 2.5	95% UCL-H
5 ≤ N < 30	S ≥ 2.5	Maximum of quantities: 99% UCL-Cheby-mv or 99% UCL-Cheby
30 ≤ N < 70	S ≥ 2.5	Maximum of quantities: 95% UCL-Cheby-mv or 95% UCL-Cheby
N ≥ 70	S ≥ 2.5	95% UCL-H

For data considered to be lognormal, the standard deviation of the log-transformed sample set was determined as follows:

$$S = \sqrt{\sum\left(\frac{(X_i - m)^2}{n-1}\right)}$$

where:

S	=	Standard deviation of the log-transformed data
X_i	=	Individual sample value (log-transformed)
μ	=	Arithmetic mean of the log-transformed n samples
n	=	Number of samples

If the EPC was based on the 95 percent H-statistic upper confidence limit on log transformed data (95 percent UCL-H), this quantity was then calculated as follows:

$$95\%UCL - H = e^{\left[m + 0.5S^2 + \left(\frac{SH}{\sqrt{n-1}}\right)\right]}$$

where:

e	=	constant (base of the natural log, equal to 2.718)
μ	=	Arithmetic mean of the log-transformed data
H	=	H-statistic (e.g., from table published in Gilbert, 1987)
S	=	Standard deviation of the log-transformed data
n	=	Number of samples

Most of the lognormal cases listed above required use of upper confidence limits based on Chebychev equations using minimum variance unbiased estimates (95 percent UCL-Cheby-mv or 99 percent UCL-Cheby-mv). In these cases, the mean and standard deviation were calculated in a different manner. For the Chebychev confidence limits, the following equations were used to calculate the minimum variance unbiased estimates of the population's mean (mean-T) and standard deviation (sigma-mv) for lognormally distributed data, according to Gilbert (1987):

Mean-T = $\exp\{:_L\}◀\!\!|_n(s_y^2/2)$

Where: $:_L$ = arithmetic mean of log-transformed data

s_y = standard deviation of log-transformed data

$◀\!\!|_n(t)$, with $t = s_y^2/2$, is the infinite series:

$◀\!\!|_n(t)$ = $1 + (n-1)t/n + (n-1)^3t^2/(2!n^2(n+1)) + (n-1)^5t^3/(3!n^3(n+1)(n+3)) + (n-1)^7t^4/(4!n^4(n+1)(n+3)(n+5)) + \ldots$

Sigma-mv = $\exp\{2*\bar{y}_L\}*[\ \hat{\delta}_n\{2s_y^2\} - \hat{\delta}_n\{\ s_y^2(n-2)/(n-1)\}\ ]$

Where: $\bar{y}_L$ = arithmetic mean of log-transformed data

s_y = standard deviation of log-transformed data

$\hat{\delta}_n(t)$, with $t = 2s_y^2$ or $t = s_y^2(n-2)/(n-1)$, is the infinite series:

$\hat{\delta}_n(t) = 1 + (n-1)t/n + (n-1)^3t^2/(2!n^2(n+1)) + (n-1)^5t^3/(3!n^3(n+1)(n+3)) + (n-1)^7t^4/(4!n^4(n+1)(n+3)(n+5)) + \ldots$

The Chebychev upper confidence limits were then estimated using the following equations, according to Singh (1999):

$$95\%UCL - Chebymv = meanT + sigmamv \times \sqrt{\frac{1}{0.05 \times N}}$$

$$99\%UCL - Chebymv = meanT + sigmamv \times \sqrt{\frac{1}{0.01 \times N}}$$

If the data were considered to be neither normally nor lognormally distributed, then the EPC was selected following a decision scheme listed below. If the standard deviation of the log transformed data was less than 0.5, then the EPC was calculated assuming a normal distribution and the 95 % UCL using the t-distribution, as delineated earlier. Otherwise, the EPC was based on either the Chebychev 95 percent confidence limit (95 percent UCL-Cheby), the Chebychev 97.5 percent confidence limit (97.5 percent UCL-Cheby), or the Chebychev 99 percent confidence limit (99 percent UCL-Cheby). The following table presents the type of upper confidence limit chosen according to the number of data points and the observed value for the log standard deviation:

Statistical UCL Methods for Nonparametrically Distributed Data

No. of Data Points	Log Standard Deviation	Type of UCL
N < 5	--	Maximum value
N ≥ 5	S < 0.5	95% UCL-N
N ≥ 5	0.5 ≤ S < 1.0	95% UCL-Cheby
N ≥ 5	1.0 ≤ S < 2.0	97.5% UCL-Cheby
N ≥ 5	S ≥ 2.0	99% UCL-Cheby

For data considered to be nonparametric, the standard deviation of the log-transformed sample set was determined as follows:

$$S = \sqrt{\sum\left(\frac{(X_i - m)^2}{n-1}\right)}$$

where:

S	=	Standard deviation of the log-transformed data
X_i	=	Individual sample value (log-transformed)
μ	=	Arithmetic mean of the log-transformed n samples
n	=	Number of samples

Wherever the nonparametric case required use of upper confidence limits based on Chebychev equations, the EPC was based on either the Chebychev 95 percent, 97.5 percent, or 99 percent confidence limits. In these cases, the mean and standard deviation were calculated in the conventional manner used for a normal distribution.

The Chebychev upper confidence limits were then estimated using the following equations, according to Singh (1999):

$$95\%UCL - Cheby = \mu + S \times \sqrt{\frac{1}{0.05 \times N}}$$

$$97.5\%UCL - Cheby = \mu + S \times \sqrt{\frac{1}{0.025 \times N}}$$

$$99\%UCL - Cheby = \mu + S \times \sqrt{\frac{1}{0.01 \times N}}$$

where:

S	=	Standard deviation of the original (not transformed) data
μ	=	Arithmetic mean of the original (not transformed) sample data
N	=	Number of samples

7.3.3 Optional Use of Maximum Observed Concentration

The preceding decision scheme was used to generate statistical estimates of the UCL for each COPC in accordance with recent guidance (EPA, 2002a, 2002b). In most, but not all cases, this approach produces statistical UCL estimates that are not unrealistically high, which is one of the main goals of the recent guidance. In contrast, earlier guidance (EPA, 1992e) specified that the H-distribution be applied to

UCLs for all lognormal and nonparametric cases and had a drawback of frequently generating extremely high UCLs greater than the maximum detected concentration.

To prevent unrealistically high EPCs at the WOD site, if the statistical UCL was greater the maximum observed concentration, then the maximum was selected as the default EPC. This optional step is allowed in current guidance (EPA, 2002a), but there is a caveat that this may yield a reasonable EPC estimate only if the sample size is sufficiently large and samples have been collected at random from the exposure unit.

7.3.4 EPCs Selected for WOD Groundwater, Surface Soil, and Soil*

Tables 7.4, 7.5, and 7.6 present the RME and CTE EPCs selected for WOD surface soil, soil* (mixture of surface and subsurface soil), and groundwater, respectively. The columns labeled rationale for selecting the EPC indicate the applicable factors that determine the EPC decision for each COPC, including number of data points, log standard deviation, and comparison of distributional test scores for normal data (Wno), lognormal data (Wlg), and lookup table values (Wt). Appendix G contains comparisons of various UCL estimates for each detected chemical and associated values of the aforementioned parameters involved in the UCL decision scheme.

7.4 EXPOSURE ASSESSMENT

The exposure assessment evaluates the potential for human exposure to the chemicals detected in the environmental media of concern at the WOD Site investigated during the RI. This section presents a characterization of the exposure setting, characterizes the exposed populations, identifies actual or potential exposure routes, and summarizes the methods used to generate exposure estimates. To determine whether there is an actual or potential exposure, the most likely pathways of contaminant release and transport, as well as the human and environmental activity patterns, are considered. A complete exposure pathway has three components: a source, a route of transport, and an exposure point for receptors. These components are addressed in this section.

7.4.1 Characterization of the Exposure Setting

A general description of the facility, its setting, and its surroundings is provided in Section 2.0 of the work plan (TtNUS, 2003a). Section 3.0 of the work plan includes a characterization of WOD site conditions, including physiography and topography, climate, soil, surface-water hydrology, and public water supply and use.

7.4.2 Potential Receptors

The receptors chosen for the WOD site are presented in this section. All of the receptors listed below are applicable to the WOD site because all selected media were sampled at the site. The potential exposure scenarios are as follows:

- Current and future Industrial Worker - The full-time onsite worker is an adult who works at WFF year round. This receptor is potentially exposed via incidental ingestion of, dermal contact with, and particulate dust inhalation of COPCs in surface soil. Examples of potential activities include groundskeeping and lawn maintenance near the airfield, installation or maintenance of airfield equipment, and utility or padwork. Inhalation of VOCs from vapor emissions from soil was not considered a significant pathway of exposure because VOCs were detected infrequently and at low concentrations in soil at the WOD. Exposure frequency for the current industrial worker is anticipated to be less than 39 days per year because only intermittent occupational activities are related to maintenance of the nearby active runway, while a hypothetical future industrial worker might be involved in a broad range of worker activities up to 250 days per year under less restricted land use scenarios. However, this future exposure scenario is only hypothetical because the area is expected to remain an active runway in the foreseeable future.

  Groundwater ingestion was not evaluated under the industrial worker scenarios because the WOD is located at the end of an active runway where no buildings are present or expected to be constructed. In addition, it is unlikely or not reasonable to assume that potable water wells for commercial/industrial purposes would be installed at the WOD because the shallow aquifer is a low-yielding aquifer and use of the aquifer is controlled and restricted by Virginia through issuances of permits under the Groundwater Management Act. In addition, public water is available at the site. The unlikely use of groundwater is evaluated under the residential scenario.

- Future Construction Worker - A future construction worker is an adult who is assumed to work at WFF involved with any type of excavation activity. This receptor is potentially exposed to disturbed soil represented by a mixture of surface soil and subsurface soil. The future construction worker may be exposed via incidental ingestion of, dermal contact with, and particulate dust inhalation of COPCs in disturbed soil. Additionally, this receptor is potentially exposed via dermal contact with contaminants in groundwater and inhalation of VOCs in shallow groundwater during excavation activities. Inhalation of VOCs from vapor emissions from soil was not considered a significant pathway of exposure because VOCs were detected infrequently and at low concentrations in soil at the WOD.

- Future Resident - A future resident is a person who will live in a residence located at or near WFF in a hypothetical future scenario. This receptor occupies a residence as a child (from age 0 - 6 years) and as an adult (for 24 years exposure duration). This receptor is potentially exposed to COPCs in groundwater via tap water ingestion, dermal contact while bathing, and inhalation of VOCs present in vapors generated during showering (adult resident only). In addition, the future resident is potentially exposed via incidental ingestion of, dermal contact with, and particulate dust inhalation of COPCs in surface soil. Inhalation of VOCs from vapor emissions from soil is not considered a significant pathway of exposure because VOCs were detected infrequently and at low concentrations in soil at the WOD. Non-cancer risks were estimated separately for child versus adult, whereas, cancer risks were considered cumulative (risks were summed over child and adult periods of exposure). Additionally, potential exposure to disturbed soil that is a mixture of surface and subsurface soils as a result of construction or landscaping activities was addressed.

- In accordance with the WOD Supplemental RI work plan, potential exposures to the surface water pathway near the WOD were not considered in this risk assessment. The only exposures to this pathway near the WOD would involve contact with surface water or sediment within an unnamed tributary or Little Mosquito Creek. Risk assessments of both areas were previously presented within the WFF Site 14 and 15 RI report that has been submitted to the EPA and VADEQ and is undergoing review, comment, and finalization. WFF Sites 14 and 15 have a greater potential for direct impact to these area surface waters than the WOD and for this reason no further sampling or assessment was proposed as part of the WOD RI.

7.4.3 Exposure Estimates

The estimation routes, methods, and models presented in this section are consistent with current EPA risk assessment guidance (EPA, 1989a, 1991b, 1992c, 1993a, 1994b, 1995, 1996b, 1996c, 1997b, and 2001a). Exposure estimates associated with each exposure route are presented below. All exposure scenarios incorporate RME and CTE EPCs in the estimation of intakes. There are three environmental media for WFF through which potential receptors (see previous section) can be either directly or indirectly exposed to site-related COPCs: groundwater, surface soil, and soil* (disturbed soil with a composition represented by a mixture of surface soil and subsurface soil). Note that disturbed soil was considered to represent only samples collected at depths less than 15 feet, consistent with VADEQ exposure assessment guidelines that are based upon a 15 foot depth of soil excavation for building foundations.

Noncarcinogenic risks are estimated using the concept of an average annual exposure. The intake incorporates terms describing the exposure time and/or frequency that represent the number of hours per day and the number of days per year that exposure occurs. This is used along with the "averaging time",

which converts the total annual exposure to an average daily dose by dividing by 365 days per year of exposure. Noncarcinogenic risks for some exposure routes (e.g., soil) are generally greater for children than for adults because of differences in body weight and intake. Carcinogenic risks, on the other hand, are estimated as an incremental lifetime risk and, therefore, incorporate terms to average the exposure duration (years) over the course of a lifetime (70 years).

7.4.4 Groundwater Exposure Estimates

Four potential exposure routes are associated with groundwater at the WOD:

- Ingestion
- Dermal absorption
- Inhalation of airborne vapors during showering
- Inhalation of VOCs in shallow groundwater during excavation

For groundwater, future construction workers were evaluated only for dermal absorption and inhalation of VOCs in shallow groundwater during excavation because incidental ingestion of groundwater during construction is not expected to result in significant intake of groundwater. Several exposure pathways were evaluated for the future resident: Tap water ingestion and dermal absorption while bathing or showering were evaluated for a future residential child, future residential adult, and future lifetime resident (cancer risk only). Additionally, for groundwater, inhalation of airborne vapors during showering was evaluated for a future residential adult. While future residential land use is not anticipated at the WOD, the degree of exposure to contaminants by residential receptors would be greater than with other exposure scenarios, so that a residential exposure evaluation conservatively assesses whether there is any need for institutional controls or other remedial measures under all possible future exposure scenarios that might occur at the WOD.

Tables 7.7 and 7.8 present the RME and CTE input parameters selected for groundwater ingestion and dermal exposure pathways, respectively, for a residential child. Tables 7.9 and 7.10 present the RME and CTE input parameters selected for groundwater ingestion and dermal exposure pathways, respectively, for a residential adult. Table 7.11 presents the RME and CTE input parameters selected for the groundwater inhalation exposure pathway for a residential adult. Table 7.12 presents the RME and CTE input parameters selected for dermal exposure to shallow groundwater during excavation by a construction worker. Table 7.13 presents the RME and CTE input parameters selected for the inhalation of VOCs in shallow groundwater during excavation.

For the groundwater exposure pathways, the following items are noteworthy:

- Chemical-specific permeability constants associated with modeling of dermal absorption are not shown on the exposure input tables. The dermal permeability constants were obtained from EPA RAGS Part E, Draft Dermal Exposure Guidance (EPA, 2001a) and are presented in Appendix G for each COPC.

- Derivations of the surface areas used in all dermal exposure equations in this risk evaluation for each potential receptor are based on surface areas for available body parts. Surface areas were extracted from dermal guidance (EPA, 2001a) for each potential receptor:

- Chemical-specific parameters associated with modeling of inhalation of airborne vapors during showering are not shown on the exposure input tables. Henry's Law constants and other parameters used in this model are obtained from several sources, including EPA (1996c) and Foster and Chrostowski (1987) and are presented in Appendix G for each COPC. Henry's Law constants published for 25 degrees C were are corrected to account for an elevated showering temperature of 45 degrees C (EPA, 2001b and Sander, 1999).

- The ASTM Guidance (Designation E 1739-95) presents the model parameters for determination of a volatilization rate of VOCs from groundwater into air. The following equations were utilized:

$$VF = \frac{H'}{1+\left[\frac{U_{air} * S_{air} * L_{GW}}{W * D_{EFF-WS}}\right]} * 10^3 \, L/m^3$$

Where:

VF = Volatilization Factor for VOC in groundwater

H' = dimensionless Henry's Law constant for VOC at 25 degrees C

U_{air} = 470 cm/sec = wind speed above ground surface in the mixing zone

S_{air} = 200 cm = ambient mixing zone

L_{GW} = 0.1 cm = depth to groundwater, $h_v + h_{cap}$

h_v = 0 cm = thickness of the vadose zone

h_{cap} = 0.1 cm = thickness of the capillary fringe

D_{EFF-WS} = effective diffusion between GW and Soil for VOC

W = 1500 cm = width of the source parallel to groundwater flow direction

$$D_{EFF-WS} = \left(h_{cap} + h_v\right) * \left[\frac{h_{cap}}{D_{EFF-cap}} + \frac{h_v}{D_{EFF-s}}\right]^{-1}$$

Where:

D_{EFF-WS} = effective diffusion between GW and Soil for VOC

h_v = 0 cm = thickness of the vadose zone

h_{cap} = 0.1 cm = thickness of the capillary fringe

$D_{EFF-cap}$ = effective diffusion through capillary fringe for VOC

D_{EFF-s} = cm2/sec = effective diffusion in soil based on vapor-phase concentration, chemical specific

Because h_v is equal to zero, this equation reduces to show that the effective diffusion between groundwater and surface soil (D_{EFF-WS}) is equal to the effective diffusion through the capillary fringe ($D_{EFF-cap}$).

$$D_{EFF-cap} = \left[D^{air} * \frac{Oa_{cap}^{3.33}}{Ot^2}\right] + \left[D^{wat} * \frac{1}{H'} * \left(\frac{Ow_{cap}^{3.33}}{Ot^2}\right)\right]$$

Where:

$D_{EFF-cap}$ = effective diffusion through capillary fringe for VOC

D^{air} = cm^2/sec = diffusion coefficient in air for VOC

D^{wat} = cm^2/sec = diffusion coefficient in water for VOC

H' = dimensionless Henry's Law constant for VOC

Oa_{cap} = 0.038 cm^3-air/cm^3-soil = volumetric air content in capillary fringe soils (equals Ot minus Oa_{cap})

Ow_{cap} = 0.342 cm^3-H2O/cm^3-soil = volumetric water content in capillary fringe soils

Ot = 0.38 cm^3/cm^3-soil = total soil porosity

7.4.5 Surface Soil and Disturbed Soil Exposure Estimates

Three potential exposure routes are associated with direct exposure to surface soil and disturbed soil at the WOD, including:

- Ingestion
- Dermal absorption
- Inhalation of fugitive dust

For disturbed soil (with a composition represented by a mixture of surface soil and subsurface soil), incidental ingestion, dermal absorption, and inhalation of fugitive dust were evaluated for a future

residential child, future residential adult, future lifetime resident (cancer risk only), and a future adult construction worker. For surface soil, ingestion, dermal absorption, and inhalation of fugitive dust were evaluated for a future residential child, future residential adult, future lifetime resident (cancer risk only), and a current/future adult industrial worker. For soil, VOCs were detected infrequently at trace levels. Therefore, inhalation exposure to VOC emissions from soil is expected to be negligible at the WOD, with ingestion and dermal absorption contributing to the majority of potential risks.

Tables 7.14, 7.15, and 7.16 present the RME and CTE input parameters for a residential child exposed to COPCs in soil (either surface soil or disturbed soil) via incidental ingestion, dermal contact, and inhalation of particulate dusts, respectively. Tables 7.17, 7.18, and 7.19 present the RME and CTE input parameters for a residential adult exposed to COPCs in soil (either surface soil or disturbed soil) via incidental ingestion, dermal contact, and inhalation of particulate dusts, respectively. Tables 7.20, 7.21, and 7.22 present the RME and CTE input parameters for a current industrial worker (groundskeeper or maintenance worker) exposed to COPCs in surface soil via incidental ingestion, dermal contact, and inhalation of particulate dusts, respectively. Tables 7.23, 7.24, and 7.25 present the RME and CTE input parameters for a future industrial worker (groundskeeper or maintenance worker) exposed to COPCs in surface soil via incidental ingestion, dermal contact, and inhalation of particulate dusts, respectively. Tables 7.26, 7.27, and 7.28 present the RME and CTE input parameters for a construction worker exposed to COPCs in disturbed soil via incidental ingestion, dermal contact, and inhalation of particulate dusts, respectively. For surface soil and disturbed soil exposure pathways, the following items are noteworthy:

- Chemical-specific absorption factors associated with dermal absorption were not shown on the exposure input tables. These values are provided in EPA dermal exposure guidance (EPA, 2001a) and specific EPA Region 3 guidance (EPA, 1995) and are presented in Section 7.5.

- The site-specific particulate emission factor (PEF) associated with modeling inhalation of fugitive dust was derived based on information presented in EPA's Soil Screening Guidance (EPA, 1996b) and site-specific information. The PEF was calculated as follows:

$$PEF(m^3/kg) = \frac{Q/C \times 3600 s/h}{\mathrm{E}_{10}}$$

where:

PEF	=	1.70 x 10^8 m^3/kg	= Site-specific particulate emission factor for WOD Site
Q/C	=	90.24 (g/m^2-s)/(kg/m^3)	= Inverse of the mean conc. at the center of a 0.5 acre source (Q/C climate zones table in EPA, 1996b)

E_{10}	=	0.036 x (1-V) x $(U_m /Ut)^3$ x F(x)	= Particulates less than 10 microns (PM_{10}) average annual emission flux (g/m^2-hr)
V	=	0.8	= Fraction of Vegetative cover
U_m	=	4.7 m/sec	= Mean Annual Windspeed at 7 m (Table 4-1, Cowherd)
U_t	=	7.44 m/s	= Threshold value of windspeed at 7 m for WOD (from equation, below)
F(x)	=	1.05	= Function of x, where x = 0.886 x Ut/U_m = 1.40 (From Figure 4-3, Cowherd)
Ut	=	U* x (1/0.4) x ln (z/z_0)	

where:

Ut	=	7.44 m/s	= Wind speed at height z for WOD
z	=	700 cm	= Height above surface (Cowherd)
z_0	=	6 cm	= Roughness height for site conditions: WOD assume 6 cm due to tall vegetation and surrounding woods and hills (Figure 3-6, Cowherd)
U*	=	0.625 m/s	= Friction velocity for assumed particle size 0.5mm (Figure 3-4, Cowherd), corrected x 1.25 (EPA, 1996b)

- Derivations of the surface areas used in all dermal exposure equations for each potential receptor were based on surface areas for available body parts. Surface areas were compiled from EPA sources (EPA, 2001a and 1997b) and are presented on the aforementioned tables for each receptor.

7.4.6 Blood-Lead Modeling

As outlined in OSWER Directive 9355.4-12, EPA (1994a) has developed an approach to evaluating lead risks that recognizes the multimedia nature of lead exposures, incorporating absorption and pharmacokinetic information. Research has been conducted concerning lead intake and resultant blood-lead levels. Determinations of lead uptake from soil and drinking water were considered. Potential blood-lead level increases are presented in Section 7.6, along with the potential implications of blood-lead results for residential children and industrial adults (pregnant females). The following discussion presents information that is useful in estimating lead exposure.

No threshold has been defined for effects related to blood-lead increases. Effects below blood-lead levels of 10 ug/dL are difficult to define. Inhibition of certain enzymes involved in red blood cell

metabolism has been reported to occur at 10 to 15 ug/dL and possibly lower. Small increases in blood pressure have been observed in adults with blood-lead levels down to 7 ug/dL (EPA, 1994b). The most sensitive subpopulation to effects below 7 ug/dL would be infants, whose early neurological development can be affected by blood-lead concentrations reportedly down to 5 ug/dL (EPA, 1994b). Lead is also a fairly common environmental contaminant and, for this reason, typical blood-lead levels in the population at large may already exceed the concentrations discussed here.

For drinking water exposure, children 0 through 6 months old are expected to experience blood-lead increases at the rate of 0.26 ug/dL per ug/L lead in water up to 15 ug/L and at the rate of 0.04 ug/dL for every ug/L lead in water above 15 ug/L (EPA, 1994b). For older children, the ratio is 0.12 ug/dL blood lead per ug/L lead in water up to 15 ug/L and 0.06 ug/dL for every ug/L lead in water above 15 ug/L (EPA, 1994b). For adults, the ratio is approximately 0.06 ug/dL blood lead per ug/L in water (EPA, 1994b). Dietary intake of lead is assumed to produce increases of 0.02 to 0.04 ug/dL blood lead per ug/day ingested by adults and 0.16 ug/dL blood lead per ug/day ingested by infants (EPA, 1986a). Blood-lead levels are estimated to increase by 0.6 to 6.8 ug/dL per 1,000 mg/kg lead in soil (EPA, 1986a).

Blood-lead levels in residential children (age 0 to 6) were estimated using the Integrated Exposure and Uptake Biokinetic (IEUBK) Model (version 1.0) developed by EPA (EPA, 1994b). The model was applied using the average groundwater and either surface soil or disturbed soil concentrations in each applicable medium of concern where lead was selected as a COPC at the WOD Site.

For the assessment of ingestion of lead in groundwater and either disturbed soil or surface soil by residential children, default values in the model were used to represent background lead concentrations in air, house dust, and the level of maternal contribution. Additionally, the model's default values were used to represent respiratory rate, soil and water ingestion rates, and the percent of lead absorption by the various exposure routes. The only site-specific factors put into the IEUBK Model were the average lead concentration in groundwater and soil.

The output of the IEUBK Model is a histogram that presents the estimated percentage of residential children (age 0 through 6 years) with a blood-lead level above 10 ug/dL (considered to be the threshold significance level above which adverse effects cannot be ruled out). When the percentage of the population estimated to have blood-levels above 10 ug/dL is greater than five percent, then EPA considers the potential for adverse effects to be significant (EPA, 1994a). These histograms, along with input information particular to each run of the IEUBK model, are presented in Appendix G, along with the estimated percentages of residential children (age 0 through 6 years) with blood-lead levels above 10 ug/dL. Uncertainties associated with the IEUBK model are discussed in Section 7.7.

Noncarcinogenic risks for industrial worker exposures to lead in surface soil or disturbed soil can be estimated using the Interim Approach to Assessing Risks Associated with Adult Exposures to Lead in Soil (EPA, 1996b). The model is based on a biokinetic slope factor that estimates fetal blood lead concentration in women exposed to lead in contaminated media. A simplified (linear) representation of lead biokinetics is used to predict quasi-steady state blood lead concentrations among adults who have relatively steady patterns of lead exposure (exposure duration of at least 90 days and exposure frequencies greater than once per week). The intake assumptions used in the model are average lead concentrations in each in soil, the ingestion rate, and an exposure frequency. Note that lead was not selected as a COPC in surface soil or disturbed soil so no estimates were generated.

The biokinetic model input parameters are a biokinetic slope factor (ug/dl adult blood lead per ug/day uptake) of 0.4, a constant of proportionality between fetal blood lead concentration at birth and maternal blood lead concentration of 0.9, a soil absorption factor of 0.12 (equal to the product of the relative bioavailability of 0.6 and a soluble lead absorption factor of 0.2), a background blood lead (typical concentration for women of child bearing age not exposed to the site) of 1.7 ug/dl, and a geometric standard deviation ranging from 1.8 (representative of homogeneous population demographics). Blood lead predictions can provide an estimate of the 95th percentile of blood lead concentrations among fetuses born to women having site exposures.

7.5 TOXICITY ASSESSMENT

Toxicity Assessment identifies the potential health hazards associated with exposure to each of the COPCs. A toxicological evaluation characterizes the inherent toxicity of a compound. The literature indicates that the COPCs have the potential to cause carcinogenic and/or noncarcinogenic health effects in humans. Although the COPCs may cause adverse health effects, dose-response relationships and the potential for exposure must be evaluated before the risks to receptors can be determined. Dose-response relationships correlate the magnitude of the intake with the probability of toxic effects, as discussed below. Toxicity information for the COPCs in groundwater, surface soil, and disturbed soil at the WOD Site are presented in Tables 7.29, 7.30, 7.31, and 7.32 (RAGs D Tables 5.1, 5.2, 6.1, and 6.2, respectively).

An important component of the risk assessment process is the relationship between the intake of a compound (the amount of a chemical that is absorbed by a receptor) and the potential for adverse health effects resulting from exposure to that dose. Dose-response relationships provide a means by which potential public health impacts can be quantified. The published information of doses and responses is used in conjunction with information on the nature and magnitude of human exposure to develop an estimate of potential health risks.

Dose-response values [reference doses (RfDs) and slope factors (SFs)] have been developed by EPA and other sources for many organics and inorganics. This section provides a brief description of these parameters.

7.5.1 Reference Doses

The RfD is developed by EPA for chronic and/or subchronic human exposure to hazardous chemicals and is based solely on the noncarcinogenic effects of chemical substances. Subchronic RfDs are specifically developed to be protective for a portion of a lifetime exposure to a compound (as a Superfund program guideline, short term). Chronic RfDs are specifically developed to be protective for long-term exposure to a compound (as a Superfund program guideline, long term). The RfD is usually expressed as a dose (mg) per unit body weight (kg) per unit time (day). It is generally derived by dividing a No-Observed-(Adverse)-Effect-Level (NOAEL or NOEL) or a Lowest-Observed-Adverse-Effect-Level (LOAEL) by an appropriate uncertainty factor. NOAELs, etc. are determined from laboratory or epidemiological toxicity studies. The uncertainty factor is based on the availability of toxicity data.

Uncertainty factors are generally applied as multiples of 10 to represent specific areas of uncertainty in the available data. A factor of 10 is used to account for variations in the general population (to protect sensitive subpopulations), when test results from animals are extrapolated to humans (to account for interspecies variability), when a NOAEL derived from a subchronic study (instead of a chronic study) is used to develop the RfD, and when a LOAEL is used instead of a NOAEL. In addition, EPA reserves the use of a modifying factor of up to 10 for professional judgment of uncertainties in the database not already accounted for. The default value of the modifying factor is 1.

The RfD incorporates the surety of the evidence for chronic human health effects. Even if applicable human data exist, the RfD (as diminished by the uncertainty factor) still maintains a margin of safety so that chronic human health effects are not underestimated. Thus, the RfD is an acceptable guideline for evaluation of noncarcinogenic risk, although the associated uncertainties preclude its use for precise risk quantitation. Oral and dermal RfDs, primary target organs, uncertainty/modifying factors, and sources of noncancer toxicity information for COPCs are provided in Table 7.29 (RAGs D Table 5.1). Inhalation RfDs, primary target organs, uncertainty/modifying factors, and sources of toxicity information for selected COPCs in soil are provided in Table 7.30 (RAGs D Table 5.2). Inhalation RfDs (mg/kg/day) were derived from inhalation reference concentrations (RfCs) (mg/m^3) by dividing by 70 kg (an assumed human body weight), multiplying by 20 m^3/day (an assumed human inhalation rate), and adjusting by an appropriate absorption factor (EPA, 1997a).

Target organ data have been extracted from the Integrated Risk Information System (IRIS; EPA, 2003), Health Effect Assessment Summary Tables (HEAST; EPA, 1997a), or other applicable sources. Only the target organs that are affected in the applicable study in which the RfD was derived have been included in Tables 7.29 and 7.30 (RAGs D Tables 5.1 and 5.2, respectively).

Noncarcinogenic risks for lead were not quantified and compared to RfDs, because EPA has implemented an approach to evaluating lead risks that does not provide a single-point estimate output. Instead, potential lead exposures are evaluated using a biokinetic model to estimate expected blood-lead increases. The blood-lead model is discussed in Section 7.4.6. A discussion of the results of the blood-lead model estimates is presented in Section 7.6.

7.5.2 Cancer Slope Factors (SFs)

SFs are applicable for estimating the lifetime probability (assumed 70-year lifespan) of human receptors developing cancer as a result of exposure to known or potential carcinogens. This factor is generally reported in units of 1/(mg/kg/day) and is derived through an assumed low-dosage linear relationship of extrapolation from high to low dose responses determined from animal studies. The value used in reporting the slope factor is the upper 95 percent confidence limit.

Oral and dermal SFs, weight of evidence, and sources of toxicity information for selected COPCs in groundwater, surface soil, and disturbed soil are provided in Table 7.31 (RAGs D Table 6.1). Inhalation SFs, weight of evidence, and sources of toxicity information for selected COPCs in groundwater, surface soil, and disturbed soil are provided in Table 7.32 (RAGs D Table 6.2). Inhalation SFs $(mg/kg/day)^{-1}$ were derived from inhalation unit risks $(ug/m^3)^{-1}$ by multiplying by 70 kg (an assumed human body weight), dividing by 20 m^3/day (an assumed human inhalation rate), and multiplying by the appropriate conversion factor (1000 ug/mg) (EPA, 1997a).

Carcinogenic risks for lead were not quantified, because EPA has not published a SF for inorganic lead. Instead, potential lead exposures were evaluated using a biokinetic model to estimate expected blood-lead increases. A discussion of these results is presented in Section 7.6.

7.5.3 EPA Weight of Evidence

The weight-of-evidence designations indicate the preponderance of evidence regarding carcinogenic effects in humans and animals. The categories are defined as follows (EPA, 1992a):

WEIGHT OF EVIDENCE CATEGORY	DEFINITION
A	Known human carcinogen
B1	Probably human carcinogen, limited human data are available
B2	Probable human carcinogen, sufficient animal data are available but inadequate human data are available
C	Possible human carcinogen
D	Not classifiable as to human carcinogenicity
E	Evidence of noncarcinogenicity in humans

7.5.4 Adjustment of Dose-Response Parameters for Dermal Exposure

Risks associated with dermal exposures were evaluated using toxicity values that are specific to absorbed dermal doses. Most oral toxicity values are based on administered doses rather than absorbed doses. Therefore, in accordance with EPA Region 3 (1995) and EPA (1989a and 2001) guidance, the toxicity values based on administered doses were adjusted before they were used for evaluating absorbed doses.

Dermal RfDs and SFs were obtained from oral RfDs and SFs via the following relationships:

$$RfD_{Adjusted} = RfD_{Oral} * GI_{Oral}$$

$$SF_{Adjusted} = SF_{Oral} / GI_{Oral}$$

where:

GI_{Oral} = Gastrointestinal (GI) Absorption Efficiency (EPA, 1995)

RfD_{Oral} = Oral Reference Dose (EPA, 2003a; EPA, 2003b; EPA, 1997a; or EPA-NCEA)

SF_{Oral} = Oral Slope Factor (EPA, 2003a; EPA, 2003b; EPA, 1997a; or EPA-NCEA)

Dermally adjusted RfDs and SFs for COPCs are presented in Tables 7.29 (RAGs D Table 5.1) and 7.31 (RAGs D Table 6.1), respectively.

7.5.5 Toxicity Criteria for Chromium

The toxicity criteria for hexavalent chromium (Cr^{+6}) were used in this risk assessment because speciation data (i.e., trivalent versus hexavalent) were not available for samples collected in areas/media of concern at the WOD Site. Hexavalent chromium was considered to be more toxic than trivalent chromium, therefore, this assumption is conservative in nature.

7.5.6 Toxicity Criteria for Mercury

The toxicity criteria for methyl mercury were used in this risk assessment because data indicating the form of mercury in environmental media was not available at the WOD Site. Methyl mercury was considered to be more toxic than inorganic mercury, therefore, this assumption is conservative in nature.

7.5.7 Carcinogenicity of PAHs

Carcinogenic PAHs are related by chemical structure. Only benzo(a)pyrene has an EPA-published SF (EPA, 2003a). All other carcinogenic PAHs, except carbazole, have SFs based on their potency relative to benzo(a)pyrene. The relative potency factors (RPF) for carcinogenic PAH COPCs at the WOD Site were as follows (EPA, 2003):

- Benzo(a)pyrene (RPF = 1.0)
- Benz(a)anthracene (RPF = 0.1)
- Benzo(b)fluoranthene (RPF = 0.1)
- Benzo(k)fluoranthene (RPF = 0.01)
- Chrysene (RPF = 0.001)
- Dibenz(a,h)anthracene (RPF = 1.0)
- Indeno(1,2,3-cd)pyrene (RPF = 0.1)

7.5.8 Constituents for Which EPA Has Not Developed Toxicity Criteria

EPA has not developed toxicity values for all chemicals for use in quantitative risk characterization. These COPCs include benzo(g,h,i)perylene and phenanthrene. Therefore, risks for these chemicals were evaluated using a surrogate (similar PAH), fluoranthene, which is consistent with previous EPA Region 3 risk assessment projects. RBC screening criteria were applied and resulted in neither substance present at a level greater than the screening criterion.

7.6 RISK CHARACTERIZATION

Potential human health risks resulting from the exposures outlined in the preceding sections are characterized on a quantitative and qualitative basis in this section. Quantitative risk estimates were generated based on risk assessment methods outlined in current EPA guidance (EPA, 1989).

Noncarcinogenic risk estimates were presented in the form of HQs and HIs that are determined through comparison of estimated intakes with published RfDs. Incremental cancer risk estimates were provided in the form of dimensionless probabilities based on SFs.

Estimated human intakes were developed for each of the specific exposure routes discussed in the preceding sections. Both noncarcinogenic and carcinogenic risks were summarized for each exposure route on a series of tables in this section.

7.6.1 Noncarcinogenic Risks

Noncarcinogenic risk was assessed using the concept of HQs and HIs. The HQ is defined as the ratio of the estimated intake and the RfD for a selected chemical of concern, as follows:

$$HQ = \frac{Intake}{RfD}$$

HIs were generated by summing the individual HQs for the COPCs. If the value of the HI exceeds unity (1.0), the potential for noncarcinogenic health risks associated with exposure to that particular chemical mixture cannot be ruled out (EPA, 1986b). In that case, particular attention should be paid to the target organ(s) affected by each chemical because these are generally the organ(s) associated with RfD-derived effects, and results (HIs) for different organs are not truly additive. The HI is not defined as a mathematical prediction of the severity of toxic effects; it is simply a numerical indicator of exceedance of the acceptable threshold for noncarcinogenic effects. Above an HI of 1, toxic effects would not necessarily occur, but can no longer be ruled out.

7.6.2 Carcinogenic Risks

Incremental cancer risk (ICR) estimates were generated for each of the exposure pathways using the estimated intakes and published SFs, as follows:

$$Risk = Intake * SF$$

If the above equation results in a risk greater than 0.01, the following equation was used:

$$Risk = 1 - e^{-(Intake * SF)}$$

The risk determined using these equations is defined as a unitless expression of an individual's increased likelihood of developing cancer as a result of exposure to carcinogenic chemicals. An ICR of 1×10^{-6} indicates that the exposed receptor has a one in a million chance of developing cancer under the defined exposure scenario. Alternatively, such a risk may be interpreted as representing one additional case of cancer in an exposed population of one million persons. The calculated cancer risks should be recognized as upper-limit estimates. SFs are defined as the upper 95 percent confidence limit of a dose-response curve generally derived from animal studies. Actual human risk, while not identifiable, is not expected to exceed the upper limit based on the SFs and may, in fact, be lower.

7.6.3 Comparison of Quantitative Risk Estimates to Benchmark Criteria

In order to interpret the quantitative risks and to aid risk managers in determining the need for remediation at a site, quantitative risk estimates are compared to typical benchmarks.

A HI exceeding unity (1) indicates that there may be potential noncarcinogenic health risks associated with exposure. If a HI exceeds unity, target organ effects from individual COPCs contributing to the risk are considered. Only those chemicals that impact the same target organ(s) or exhibit similar critical effect(s) will be regarded as truly additive. Thus, COPCs contributing to a HI greater than 1 on the basis of a single target organ/effect are considered to be chemicals of concern (COCs) to be addressed in the feasibility study (FS). Individual COCs that exhibit a HI greater than 1 typically require consideration of remediation options such as treatment/disposal, land use restrictions, monitoring of natural attenuation, or other risk management strategies. However, remediation decisions are not made strictly based on HIs but are often modified by such regulatory requirements as MCLs or chemical-specific clean-up goals.

EPA has defined the range of 1×10^{-4} to 1×10^{-6} as the incremental cancer risk (ICR) "target range" such that, when the sum of cancer risks for all COPCs in a given medium is greater than 1×10^{-4}, this generally indicates that EPA will require consideration of remediation options such as treatment/disposal, land use restrictions, monitoring of natural attenuation, or other risk management strategies. ICRs below 1×10^{-4} normally will not require initiation of remedial efforts for a given medium. Whenever the overall ICR for a medium is greater than 1×10^{-4}, individual chemicals are selected which contribute significantly to overall risk, typically those chemicals with an individual ICR greater than 1×10^{-6}, and are included in the list of COCs to be addressed in the feasibility study (FS). However, remediation decisions are not made strictly based on ICRs but are often modified by such regulatory requirements as MCLs or chemical-specific clean-up goals.

Potential RME hazard indices and RME cancer risks were estimated for current and future potential receptors. The following sections present a summary of the results of the estimation of risk at areas/media of concern at the WOD Site.

Receptor risks are presented for each media of concern in the form of tables and summary text. Each of these sections includes summaries of risks estimated by the exposure scenarios. It should be noted that, in each risk summary table where HQs are reported as "N/A", the HQs were not calculable because no RfD has been established. Usually in such cases, carcinogenicity is considered to be more important, since carcinogenicity will generally be seen at lower doses than noncarcinogenic effects. Cancer risks that are reported as "N/A" generally indicate that the chemical is not carcinogenic or that an SF has not yet been developed.

7.6.4 Site-Specific Noncarcinogenic Risks

Site-specific noncarcinogenic risks were estimated for potential receptors at the WOD Site and are discussed below. If the RME HI did not exceed 1.0 for any target organ group, then the CTE risk was not calculated for that medium and that receptor. Chemical-specific HQs, associated target organs, and the cumulative HI for each target organ are presented on tables in this section according to RAGS D Table 9 format. Supporting data including non-cancer risks, receptor dose, and EPCs for each COPC are presented on tables in Appendix G for each receptor and exposure medium according to RAGS D Table 7 format.

7.6.4.1 Surface Soil

Noncarcinogenic risks did not exceed a HI of 1.0 for any target organ group for the receptors potentially exposed to surface soils at WOD Site, including the current industrial worker, future industrial worker, residential child, and residential adult (Tables 7.33, 7.34, 7.35, and 7.36, respectively).

7.6.4.2 Soil*

Noncarcinogenic risks did not exceed a HI of 1.0 for any target organ group for the receptors potentially exposed to soil* (mixture of surface and subsurface soil) at WOD Site, including the current industrial worker, future industrial worker, construction worker, residential child, and residential adult (Tables 7.38, 7.39, 7.40, 7.41, and 7.42, respectively).

7.6.4.3 Groundwater

Noncarcinogenic risks did not exceed a HI of 1.0 for any target organ group for the construction worker potentially exposed to groundwater at WOD Site (Table 7.44).

The estimated RME HI for a future residential child exposed to groundwater at WOD was 30.1 (Table 7.45), exposure contributions primarily from ingestion (and to a lesser extent, dermal absorption), which exceeded the acceptable level of 1.0. The target organs with HIs exceeding 1.0 from ingestion exposure were blood (HI of 14.6 - primary contributor iron); liver (HI of 14.5 - primary contributor iron); GI Tract (HI of 14.4 - primary contributor iron); skin and vascular system (HI of 4.4 - primary contributor arsenic); and CNS (HI of 3.0 - primary contributors manganese, aluminum, and 4-methylphenol). In addition, chromium exhibited a HQ of 5.9 (contributions from ingestion and dermal contact), but no target organ was associated because the RfD was based upon studies that only support determination of a no-observed-adverse-effects-level (NOAEL) and not a threshold target organ effect.

The estimated CTE HI for a future residential child exposed to groundwater at WOD was 16.8 (Table 7.46), exposure contributions primarily from ingestion (and to a lesser extent, dermal absorption), which exceeded the acceptable level of 1.0. The target organs with HIs exceeding 1.0 from ingestion exposure were blood (HI of 8.3 - primary contributor iron); liver (HI of 8.3 - primary contributor iron); GI Tract (HI of 8.2 - primary contributor iron); skin and vascular system (HI of 2.5 - primary contributor arsenic); and CNS (HI of 1.7 - primary contributors manganese, aluminum, and 4-methylphenol). In addition, chromium exhibited a HQ of 3.0 (contributions from ingestion and dermal contact), but no target organ was associated because the RfD was based upon studies that only support determination of a no-observed-adverse-effects-level (NOAEL) and not a threshold target organ effect.

The estimated RME HI for a future residential adult exposed to groundwater at WOD was 14.7 (Table 7.47), with exposure contributions primarily from ingestion, inhalation during showering, and to a lesser extent, dermal absorption. The target organs with HIs exceeding 1.0 primarily from ingestion exposure were blood (HI of 4.7 - primary contributor iron); liver (HI of 4.6 - primary contributor iron); GI Tract (HI of 4.6 - primary contributor iron); and skin and vascular system (HI of 1.4 - primary contributor arsenic). In addition, the target organ CNS exhibited a HI of 1.5 - primary contributor's manganese, aluminum, and 4-methylphenol via ingestion, and xylene (total) via inhalation. The HI also exceeded the acceptable level of 1.0 for the target organ respiratory system (HI of 2.7 - primary contributor naphthalene via inhalation). In addition, chromium exhibited a HQ of 1.6 (contributions from ingestion and dermal contact), but no target organ was associated because the RfD was based upon studies that only support determination of a no-observed-adverse-effects-level (NOAEL) and not a threshold target organ effect. The HI also

exceeded the acceptable level for 1,2,4-trimethylbenzene (HQ of 1.8), but target organ data were not supplied in the reference citation (EPA Region 3 risk-based concentration tables).

The estimated CTE HI for a future residential adult exposed to groundwater at WOD was 9.3 (Table 7.48), with exposure contributions primarily from ingestion, inhalation during showering, and to a lesser extent, dermal absorption. The target organs with HIs exceeding 1.0 primarily from ingestion exposure were blood (HI of 3.3 - primary contributor iron); liver (HI of 3.2 - primary contributor iron); and GI Tract (HI of 3.2 - primary contributor iron). The HI also exceeded the acceptable level of 1.0 for the target organ respiratory system (HI of 1.4 - primary contributor naphthalene via inhalation). In addition, chromium exhibited a HQ of 1.1 (contributions from ingestion and dermal contact), but no target organ was associated because the RfD was based upon studies that only support determination of a no-observed-adverse-effects-level (NOAEL) and not a threshold target organ effect.

7.6.5 Site-Specific Cancer Risks

Site-specific cancer risks were estimated for potential receptors at the WOD Site and are discussed below. If the overall RME ICR did not exceed 1.0×10^{-4} for a given medium and receptor, then the CTE risk was not calculated for that medium/receptor. Chemical-specific ICRs are presented on tables in this section according to RAGS D Table 9 format. Supporting data including cancer risks, receptor dose, and EPCs for each COPC are presented on tables in Appendix G for each receptor and exposure medium according to RAGS D Table 8 format.

7.6.5.1 Surface Soil

The estimated RME ICR for a current adult industrial worker exposed to surface soil at WOD Site was less than EPA's target risk range of 1×10^{-4} to 1×10^{-6} (Table 7.33).

The estimated RME ICR for a future adult industrial worker exposed to surface soil at WOD Site was 1.7×10^{-6} (see Table 7.34 for contributions from ingestion, dermal contact, and inhalation of particulates). The ICR is near the lower end of EPA's target risk range of 1×10^{-4} to 1×10^{-6}. The primary contributor to the cancer risk was benzo(a)pyrene via ingestion and dermal contact.

The estimated RME ICR for a future child resident exposed to surface soil at WOD Site was 6.3×10^{-6} (see Table 7.35 for contributions from ingestion, dermal contact, and inhalation of particulates). The ICR is within EPA's target risk range of 1×10^{-4} to 1×10^{-6}. The primary contributor to the cancer risk was benzo(a)pyrene via ingestion and dermal contact.

.

The estimated RME ICR for a future adult resident exposed to surface soil at WOD Site was 2.9×10^{-6} (see Table 7.36 for contributions from ingestion, dermal contact, and inhalation of particulates). The ICR is near the lower end of EPA's target risk range of 1×10^{-4} to 1×10^{-6}. The primary contributor to the cancer risk was benzo(a)pyrene via ingestion and dermal contact.

The estimated RME ICR for a future lifetime resident exposed to surface soil at WOD Site was 9.2×10^{-6} (see Table 7.37 for contributions from ingestion, dermal contact, and inhalation of particulates). The ICR is within EPA's target risk range of 1×10^{-4} to 1×10^{-6}. The primary contributor to the cancer risk was benzo(a)pyrene via ingestion and dermal contact.

7.6.5.2 Soil*

The estimated RME ICR for a current adult industrial worker exposed to soil* (mixture of surface and subsurface soil) at WOD Site was less than EPA's target risk range of 1×10^{-4} to 1×10^{-6} (Table 7.38).

The estimated RME ICR for a future adult industrial worker exposed to soil* at WOD Site was 1.4×10^{-6} (see Table 7.39 for contributions from ingestion, dermal contact, and inhalation of particulates). The ICR is near the lower end of EPA's target risk range of 1×10^{-4} to 1×10^{-6}. The primary contributor to the cancer risk was benzo(a)pyrene via ingestion and dermal contact.

The estimated RME ICR for a construction worker exposed to soil* at WOD Site was less than EPA's target risk range of 1×10^{-4} to 1×10^{-6} (Table 7.40).

The estimated RME ICR for a future child resident exposed to soil* at WOD Site was 5.0×10^{-6} (see Table 7.41 for contributions from ingestion, dermal contact, and inhalation of particulates). The ICR is within EPA's target risk range of 1×10^{-4} to 1×10^{-6}. The primary contributor to the cancer risk was benzo(a)pyrene via ingestion and dermal contact.

The estimated RME ICR for a future adult resident exposed to soil* at WOD Site was 2.3×10^{-6} (see Table 7.42 for contributions from ingestion, dermal contact, and inhalation of particulates). The ICR is near the lower end of EPA's target risk range of 1×10^{-4} to 1×10^{-6}. The primary contributor to the cancer risk was benzo(a)pyrene via ingestion and dermal contact.

The estimated RME ICR for a future lifetime resident exposed to soil* at WOD Site was 7.3×10^{-6} (see Table 7.43 for contributions from ingestion, dermal contact, and inhalation of particulates). The ICR is within EPA's target risk range of 1×10^{-4} to 1×10^{-6}. The primary contributor to the cancer risk was benzo(a)pyrene via ingestion and dermal contact.

7.6.5.3 Groundwater

The estimated RME ICR for a future adult construction worker exposed to groundwater at WOD Site was below EPA's target risk range of 1×10^{-4} to 1×10^{-6} (see Table 7.44 for contributions from dermal contact and inhalation of VOCs in shallow groundwater during excavation activities).

The estimated RME ICR for a future child resident exposed to groundwater at WOD Site was 1.9×10^{-4} (see Table 7.45 for contributions from ingestion and dermal contact). The ICR slightly exceeds EPA's target risk range of 1×10^{-4} to 1×10^{-6}. The principal COPCs and exposure pathways contributing to the significant portion of cancer risks were arsenic via ingestion (ICR = 1.7×10^{-4}), tetrachloroethene via ingestion and dermal contact (ICR = 1.5×10^{-5}), and benzene via ingestion (ICR = 3.8×10^{-6}).

The estimated CTE ICR for a future child resident exposed to groundwater at WOD Site was 3.6×10^{-5} (see Table 7.46 for contributions from ingestion and dermal contact). The ICR is within EPA's target risk range of 1×10^{-4} to 1×10^{-6}. The principal COPCs and exposure pathways contributing to the significant portion of cancer risks were arsenic and tetrachloroethene via ingestion.

The estimated RME ICR for a future adult resident exposed to groundwater at WOD Site was 2.4×10^{-4} (see Table 7.47 for contributions from ingestion, dermal contact, and inhalation of vapors during showering). The ICR slightly exceeds EPA's target risk range of 1×10^{-4} to 1×10^{-6}. The principal COPCs and exposure pathways contributing to the significant portion of cancer risks were arsenic via ingestion (ICR = 2.1×10^{-4}), tetrachloroethene via ingestion and dermal contact (ICR = 1.6×10^{-5}), bis(2-ethylhexyl) phthalate via ingestion and dermal contact (ICR = 1.2×10^{-6}), and benzene via ingestion and inhalation (ICR = 7.25×10^{-6}).

The estimated CTE ICR for a future adult resident exposed to groundwater at WOD Site was 6.2×10^{-5} (see Table 7.48 for contributions from ingestion, dermal contact, and inhalation of vapors during showering). The ICR is within EPA's target risk range of 1×10^{-4} to 1×10^{-6}. The principal COPCs and exposure pathways contributing to the significant portion of cancer risks were arsenic via ingestion, tetrachloroethene via ingestion and dermal contact, and benzene via ingestion.

The estimated RME ICR for a future lifetime resident exposed to groundwater at WOD Site was 4.3×10^{-4} (see Table 7.49 for contributions from ingestion, dermal contact, and inhalation of vapors during showering). The ICR exceeds EPA's target risk range of 1×10^{-4} to 1×10^{-6}. The principal COPCs and exposure pathways contributing to the significant portion of cancer risks were arsenic via ingestion (ICR = 3.8×10^{-4}), tetrachloroethene via ingestion and dermal contact (ICR = 3.1×10^{-5}), bis(2-ethylhexyl)

phthalate via ingestion and dermal contact (ICR = 2.1 x 10^{-6}), and benzene via ingestion and inhalation (ICR = 1.1 x 10^{-5}).

The estimated CTE ICR for a future lifetime resident exposed to groundwater at WOD Site was 9.8 x 10^{-5} (see Table 7.50 for contributions from ingestion, dermal contact, and inhalation of vapors during showering). The ICR is near the upper end of EPA's target risk range of 1 x 10^{-4} to 1 x 10^{-6}. The principal COPCs and exposure pathways contributing to the significant portion of cancer risks were arsenic via ingestion, tetrachloroethene via ingestion and dermal contact, and benzene via ingestion.

7.6.6 Blood-Lead Risk Characterization

Blood-lead levels in residential children (age 0 through 6) were estimated using the Integrated Exposure and Uptake Biokinetic (IEUBK) Model (version 1.0) developed by EPA (EPA, 1994b). The model was applied in each applicable medium of concern where lead was selected as a COPC at the WOD Site.

Lead was selected as a COPC in groundwater but not in surface soil or disturbed soil. Therefore, for the assessment of exposures to lead in groundwater by residential children, the arithmetic mean of the WOD Site groundwater lead concentration was used (7.81 ug/L), while default values in the IEUBK model were used to represent background lead concentrations in air, house dust, and the level of maternal contribution.

The output of the IEUBK Model is a histogram that presents the estimated percentage of residential children (age 0 through 6 years) with a blood-lead level above 10 ug/dL (considered to be the threshold significance level above which adverse effects cannot be ruled out). When the percentage of the population estimated to have blood-levels above 10 ug/dL is greater than five percent, then EPA considers the potential for adverse effects to be significant (EPA, 1994a).

The estimated percentage of children exposed to groundwater that were predicted to exhibit a blood lead level above 10 ug/dL is 1.6 percent, which is less than EPA's protective level cutoff of 5%. Therefore, no adverse effects would be anticipated for a hypothetical residential child exposed to lead in groundwater via tap water consumption. Appendix G contains histograms of anticipated blood lead concentrations and tabulated estimates of lead uptake contributions for air, diet, water, soil, and dust for age intervals from 0 through 6 years old.

7.6.7 Summary of Receptor Risks and Hazards for COPCs - Risks Due to Multiple Media

Although carcinogenic and noncarcinogenic risks were summarized separately for each exposure medium in the previous sections, a more realistic scenario is that potential receptors might be exposed to more than one medium, depending upon receptor activity patterns. In this section, additive risks were estimated to show the overall risks that each individual receptor might incur as a result of exposure to multiple media at WOD Site.

7.6.7.1 Current Industrial Worker

Based on the receptor exposure pathway assumptions listed in Section 7.4, the current industrial worker may be separately exposed to COPCs found in surface soil or soil* (mixture of surface and subsurface soil) but this receptor is not anticipated to be exposed to groundwater. Therefore, it was not necessary to estimate cumulative risks associated with multiple media exposures for this receptor.

7.6.7.2 Future Industrial Worker

Based on the receptor exposure pathway assumptions listed in Section 7.4, the future industrial worker may be separately exposed to COPCs found in surface soil or soil* (mixture of surface and subsurface soil) but this receptor is not anticipated to be exposed to groundwater. Therefore, it was not necessary to estimate cumulative risks associated with multiple media exposures for this receptor.

7.6.7.3 Construction Worker

Based on the receptor exposure assumptions listed in Section 7.4, the future construction worker may be exposed to COPCs in groundwater and soil* (mixture of surface and subsurface soil). Table 7.51 presents a summation of the RME cancer risks and non-cancer HIs estimated for combined exposure to COPCs in found in these two media. For the construction worker, multiple media exposures are not expected to result in non-cancer HIs exceeding 1.0 for any target organ. In addition, the cumulative cancer risk from multiple media exposure was less than EPA's target risk range of 1×10^{-4} to 1×10^{-6}.

7.6.7.4 Residential Child

Based on the receptor exposure assumptions listed in Section 7.4, the future residential child may be exposed to either groundwater and surface soil or groundwater and soil* (mixture of surface and subsurface soil), depending upon whether soil in a hypothetical future residential neighborhood would remain largely undisturbed or mixed as a result of construction and landscaping. Cancer risks and non-

cancer HIs associated with either type of scenario -- combined exposure to COPCs in groundwater and surface soil or combined exposure to groundwater and soil* - are presented in Tables 7.52 and 7.54, respectively. For either scenario, multiple media exposures could result in non-cancer HIs exceeding 1.0 for several target organs as a result of contributions from COPCs present in groundwater, whereas contributions to HIs from COPCs in surface soil or soil* were negligible.

For a residential child exposed to groundwater and soil*, the cumulative cancer risk exceeded EPA's target risk range of 1×10^{-4} to 1×10^{-6}, but contributions to the overall cancer risk were much greater in groundwater (greater than 1×10^{-4}), whereas the soil* cancer risk was within the target risk range.

For a residential child exposed to groundwater and surface soil, the cumulative cancer risk also exceeded EPA's target risk range of 1×10^{-4} to 1×10^{-6}, but contributions to the overall cancer risk were much greater in groundwater (greater than 1×10^{-4}), whereas the surface soil cancer risk was within the target risk range.

CTE cancer risks and non-cancer HIs for the future residential child exposed to COPCs in multiple media -- groundwater/surface soil and groundwater/soil* -- are presented in Tables 7.53 and 7.55, respectively.

7.6.7.5 Residential Adult

Based on the receptor exposure assumptions listed in Section 7.4, the future residential adult may be exposed to either groundwater and surface soil or groundwater and soil* (mixture of surface and subsurface soil), depending upon whether soil in a hypothetical future residential neighborhood would remain largely undisturbed or mixed as a result of construction and landscaping. Cancer risks and non-cancer HIs associated with either type of scenario -- combined exposure to COPCs in groundwater and surface soil or combined exposure to groundwater and soil* - are presented in Tables 7.56 and 7.58, respectively. For either scenario, multiple media exposures could result in non-cancer HIs exceeding 1.0 for several target organs as a result of contributions from COPCs present in groundwater, whereas contributions to HIs from COPCs in surface soil or soil* were negligible.

For a residential adult exposed to groundwater and soil*, the cumulative cancer risk exceeded EPA's target risk range of 1×10^{-4} to 1×10^{-6}, but contributions to the overall cancer risk were much greater in groundwater (greater than 1×10^{-4}), whereas the soil* cancer risk was within the target risk range.

For a residential adult exposed to groundwater and surface soil, the cumulative cancer risk also exceeded EPA's target risk range of 1×10^{-4} to 1×10^{-6}, but contributions to the overall cancer risk were much

greater in groundwater (greater than 1 x 10^{-4}), whereas the surface soil cancer risk was within the target risk range.

CTE cancer risks and non-cancer HIs for the future residential adult exposed to COPCs in multiple media - groundwater/surface soil and groundwater/soil* -- are presented in Tables 7.57 and 7.59, respectively.

7.6.7.6 Lifetime Resident

Based on the receptor exposure assumptions listed in Section 7.4, the future lifetime resident may be exposed to either groundwater and surface soil or groundwater and soil* (mixture of surface and subsurface soil), depending upon whether soil in a hypothetical future residential neighborhood would remain largely undisturbed or mixed as a result of construction and landscaping. Cancer risks associated with either type of scenario -- combined exposure to COPCs in groundwater and surface soil or combined exposure to groundwater and soil* -- are presented in Tables 7.60 and 7.62, respectively.

For a future lifetime resident exposed to groundwater and soil*, the cumulative cancer risk exceeded EPA's target risk range of 1 x 10^{-4} to 1 x 10^{-6}, but contributions to the overall cancer risk were much greater in groundwater (greater than 1 x 10^{-4}), whereas the soil* cancer risk was within the target risk range.

For a future lifetime resident exposed to groundwater and surface soil, the cumulative cancer risk also exceeded EPA's target risk range of 1 x 10^{-4} to 1 x 10^{-6}, but contributions to the overall cancer risk were much greater in groundwater (greater than 1 x 10^{-4}), whereas the surface soil cancer risk was within the target risk range.

CTE cancer risks for the future lifetime resident exposed to COPCs in multiple media - groundwater/surface soil and groundwater/soil* -- are presented in Tables 7.61 and 7.63, respectively.

7.7 UNCERTAINTY ANALYSIS

The goal of the uncertainty analysis is to identify important uncertainties and limitations associated with the groundwater risk assessment. As discussed in EPA (1989a), the risk measures used in Superfund site risk assessments are not fully probabilistic estimates of risk but rather are conditional estimates based on a considerable number of assumptions about exposure and toxicity. There are uncertainties associated with each aspect of risk assessment, from environmental data collection through risk characterization.

7.7.1 Uncertainties Associated with Data Collection and Evaluation

Major uncertainties associated with data collection and evaluation are highlighted below.

7.7.1.1 Selection of Locations and Numbers of Samples

The areal extent of the samples (including the number collected and location of the sampling points) in a particular area or medium of interest impacts the selection of COPCs, the calculation of EPCs, and consequently the risks estimated for a site. Generally, sample collection at each area of interest or site should reflect actual site conditions and should include areas that contain the most significant contamination or exposure problems. At WOD Site, 12 monitoring wells encompass the disposal area on all sides and establish several sampling depth intervals. Older groundwater data were used to identify where data gaps existed and resulted in the installation of additional wells where needed. All groundwater wells were sampled in 2003 within a two month timeframe, which provides a representative snapshot of current groundwater conditions. While earlier investigations provided sufficient soil samples to support focused removal efforts, the supplemental soil samples collected in this investigation provided better coverage throughout the source area, in addition to indicating areas near the boundaries of site contamination. Therefore, the objectives of the Supplemental RI were met in terms of obtaining adequate numbers and locations of samples to fill in data gaps.

Surface water samples where not necessary to collect for the reasons noted in Section 7.4.

7.7.1.2 Data Collection Impacts on Selection of COPCs and Risks

While the extensive additional sampling coverage in the Supplemental RI made it unlikely that the areas of highest contamination were missed, a different potential problem could occur if too few samples were collected as background samples. There were adequate numbers of background soil samples taken to achieve statistical power in comparing site to background, but this was not the case for groundwater because of the requirement that background groundwater samples must be obtained from wells located immediately upgradient of the site rather than just anywhere in the regional area where contamination due to site-related activities was not plausible. There were only two upgradient groundwater samples collected in 2003, which was inadequate to allow background tests to confidently demonstrate evidence of metals that should be eliminated as COPCs because of similarity to background levels. Therefore, only a qualitative comparison of site versus background could be performed for metals in groundwater.

Metals found in groundwater that are not actually site-related could be selected as COPCs and site-related human health risks could be overestimated if any of the metals which are risk drivers (namely

arsenic, chromium, iron, or manganese) are attributable to background conditions. However, arsenic, chromium, and lead were not detected in upgradient samples and upgradient levels of manganese and iron were several orders of magnitude less than the maximum levels found downgradient or within the WOD site. In addition, the location of highest concentrations of BTEX and naphthalene in groundwater (WFF15-GW7) is the same as that where the highest levels were found for manganese and lead, and arsenic and iron levels were also in the top 3 ranked concentrations among WOD groundwater samples at this location. These findings are consistent with the hypothesis that reducing conditions associated with contaminant degradation might have enhanced the dissolution of naturally occurring metals from the geologic formation at one particular location, given that none of these metals were found at levels statistically greater than background in subsurface soil. Across the entire site, groundwater risks may be generally overestimated for metals because very few samples revealed elevated levels of specific metals in groundwater. In addition, maximum levels of arsenic and iron in groundwater occurred at locations removed from the vicinity of the location of BTEX groundwater detections, which is not inconsistent with the possibility that some detections of these metals might be naturally occurring as opposed to site-related.

7.7.1.3 Uncertainties Regarding the Selection of the EPC

Other uncertainties exist regarding selection of a concentration for input into the quantitative risk assessment. The use of the exposure point concentration to estimate risk is generally regarded as a conservative estimate since this entails using either the upper 95 percent confidence limit on the arithmetic mean (based on normal or log-transformed data distribution) or the maximum concentration. The choice of the exposure point concentration as the value for input into the risk assessment generally lowers the chances of underestimation of the actual risk present in a pathway at a particular area of interest to a potential receptor.

While the use of upper 95 percent statistical confidence limit on the mean may overestimate the average exposure point concentration, a decision scheme recommended in recent guidance (EPA, 2002b) was followed that reduced the degree of overestimation. Chebychev UCL estimates were generated as appropriate to each situation where the number of samples was small, the log-standard deviation was large, or when the data were non-parametrically distributed. In such cases, the traditional approach would have employed the H-distribution and would have generated unrealistically high UCLs greater than the maximum detected concentration. The newer approach successfully produced more reasonable estimates that were less than the maximum detected value in most cases.

The ability (power) of the W test to be able to correctly identify genuine differences between the shapes of a sample population versus a reference normal or lognormal population is reduced when too few samples

are collected. If an incorrect distributional assumption is made based on this test, this could lead to an over- or underestimate of the upper 95 percent concentration, which in turn would create some additional uncertainty as to whether the calculated risk is a reasonable approximation of high end exposure. If fewer than 5 samples were available, the distributional tests were not considered significant and the exposure point concentration was selected as the maximum value. The Supplemental RI included many samples of each medium, so this situation only occurred for one analyte. Groundwater data for chromium consisted of less than 5 samples, which impacts risk uncertainty because chromium was a noncarcinogenic risk driver.

Specific uncertainties are associated with low frequencies of detection for several substances that were contributors to groundwater cancer risks or noncancer HIs, in particular, detection frequencies of 1/12 (8 percent) for tetrachloroethene, 2/12 (17 percent) for benzene, and 1/8 (12 percent) for arsenic. Because UCL calculations assumed all non-detected values were positives of magnitude equal to one-half the sample quantitation limit, the resulting 95 percent UCL estimates that were adopted as the EPCs for these substances could be overestimated and the true mean of the groundwater concentrations might be somewhat lower than these EPCs would suggest. However, the degree of overestimation is not large because the maximum positive results were generally greater than 10 times the assumed one-half detection limit values. On the other hand, the EPC for chromium was based on the maximum value as opposed to a statistical UCL, but use of the maximum represents another large source of uncertainty because only one data point is being relied upon to generate an estimate of the overall potential exposure concentration.

7.7.1.4 Uncertainties in Laboratory Data Quality

Validated laboratory data were used to calculate EPCs for groundwater, surface soil, and soil* (mixture of surface and subsurface soil). Established data validation procedures were applied to define analytical uncertainties in terms of qualifying data as inaccurate or imprecise and to eliminate data points that are unusable for risk assessment. This treatment does not eliminate all uncertainty but focuses attention on potential areas of concern regarding accuracy, precision, and data gaps.

7.7.1.5 Uncertainties in Risk-Based Screening Levels

The use of single-route (ingestion) risk-based screening concentrations (RBCs) may lead to the underestimation of risks since these values do not account for the additive effects across various exposure pathways. In particular, the dermal contact and inhalation pathways are not quantitatively accounted for in the benchmark RBCs used to select or eliminate COPCs in the risk assessment. However, inhalation of outdoor air containing concentrations of organics volatilizing from groundwater or

particulate dusts generated from windblown soils are each considered very minor contributions to risk compared to the ingestion pathway.

However, the potential inaccuracy from using ingestion-based RBCs to extrapolate exposures from inhalation of VOCs during showering or dermal contact exposures is somewhat greater. Showering exposures are accounted for via a factor of two adjustments in the Region 3 RBCs, which is generally protective for most, but not all cases. In addition, it is not necessarily true that RBCs based on threshold risks due to ingestion are protective for all dermal contact exposures because of the broad range of variation in GI absorption factors, which alters the effective dermal toxicity factor, and permeability constants, which alter the effective dermal dose. However, the likelihood of underestimating the number of potentially significant COPCs based on using ingestion-based RBCs is mitigated in most cases because Region 3 adjusts the RBC screening benchmarks to a conservative endpoint derived from a target HI of 0.1 for noncarcinogens and a target risk of 1×10^{-6} for carcinogens, which incorporates one or two orders of magnitude, respectively, as a safety factor into the threshold risks associated with the adjusted RBCs.

There is uncertainty due to the lack of risk-based screening and risk estimation for indoor air exposure to VOCs from vapor intrusion. This type of exposure could occur only if land use changes and future buildings or dwellings were constructed within the WOD area, which is adjacent to an active runway. To evaluate this uncertainty, groundwater maximum contaminant levels were compared to DEQ Voluntary Remediation Program (VRP) screening levels for volatilization from groundwater to indoor air. Appendix I, Part 1 presents the results of risk-based screening for groundwater vapor intrusion based on DEQ VRP Risk Assessment Guidance, Table 2.10 for unrestricted indoor air exposure. Based on this screening, 1,2,4-trimethylbenzene and 1,3,5-trimethylbenzene exceeded DEQ's Tier II screening criteria and could be considered COPCs for the vapor intrusion pathway. Therefore, vapor intrusion risks were estimated for 1,2,4-trimethylbenzene and 1,3,5-trimethylbenzene assuming groundwater EPCs of 170 ug/L and 74 ug/L, respectively, using EPA's Johnson and Ettinger spreadsheet model, GW-SCREEN (version 3.0). Because of varied topography, the model was run twice to account for varying depth to groundwater – 12 feet as a worst case for shallowest depth, and 21 feet as recently measured in the vicinity of the most contaminated well. Appendix I, Part 1 presents the results of spreadsheet modeling for receptor risks from groundwater vapor intrusion. The spreadsheet model estimated HIs for both COPCs to be less than the target risk level (HI of 1), so in conclusion no significant adverse effects from vapor intrusion would be expect in the event that future land use changes at the WOD site.

Benzo(g,h,i)perylene and phenanthrene were detected in soil. Although published RfDs and RBCs were not available for these substances, surrogate screening RBCs were adopted using fluoranthene, a similar PAH compound associated with published RfD and RBC values. Phenanthrene and benzo(g,h,i)perylene

were both found to be present below the derived screening RBCs and so were not selected as a COPCs. Accounting for potential noncancer risks in this manner reduces the chance of underestimating risks from compounds without published toxicity factors.

7.7.2 Uncertainties Associated with Exposure Assessment

Major uncertainties associated with Exposure Assessment are listed below.

7.7.2.1 Exposure Scenarios

The likelihood of the occurrence of the defined exposure scenarios is a source of uncertainty. The future anticipated land use at WOD Site is expected to remain as NASA airfield and related light industrial activities. Likely potential receptors under this land use scenario include industrial workers or construction workers. Additionally, exposures to groundwater, soil*, and surface soil were evaluated for a hypothetical child and adult resident. This was done in order to generate an upper bound to risks from all potential uses of groundwater that is consistent with EPA and Commonwealth of Virginia standard guidelines. The degree of exposure to contaminants from the residential scenario would be greater than with other exposure scenarios; however, the continued use of the land as an airfield is anticipated and the development of the area for residential purposes is extremely unlikely.

By assessing the potential risks under a hypothetical residential exposure scenario, the risk assessment can be used to generate standards for protectiveness that are assured to encompass the full range of possible exposures that might occur at the site. However, standards for protectiveness which are based upon residential scenarios would be overly conservative if applied only to prevent adverse health risks in the situation of industrial and construction exposure scenarios. In addition, the assumption that shallow WOD groundwater (Columbia Aquifer) would be developed as a tap water source for future residences is unlikely because the lower Yorktown aquifer is more productive and use of the shallow Columbia Aquifer is discouraged and restricted by the Commonwealth of Virginia under a groundwater management program administered by the VADEQ.

The future exposure scenario contains an assumption that soils at depths less than 15 feet could eventually become a source of routine human exposure. While future construction of roads, landscaping of development areas, or excavation of typical basements for buildings and residences might result in mixing and redistribution of shallow subsurface soils, disturbance of soil below the 10 or 15-foot depth of a typical basement excavation would be improbable and hence VADEQ guidelines recommend evaluating risks associated with direct contact soil exposure only for samples from depths less than 15 feet. Therefore, it was appropriate and realistic to exclude five subsurface soil samples that were

collected at depths below 15 feet from the risk assessment. This is a very minor source of uncertainty because, if the five omitted samples were to be included in the total soils data set, then changes to cancer risks would only occur in the second significant digit.

7.7.2.2 Exposure Equations

There are limitations to using various models and equations to estimate exposure doses or contaminant concentrations. For example, the use of modeled concentrations (i.e., generated fugitive dust concentrations and generated volatile emissions) in place of monitored values may not be indicative of actual site conditions during exposure. Exposure to fugitive dust conservatively assumes that potential receptors will be exposed to the same concentration indoors as outdoors (a very conservative assumption), that soils within an area have unlimited erosion potential, that emissions can be estimated from mean annual wind speed and vegetative cover, and that dispersion concentrations can be estimated from source area, downwind distance to receptors, and region-wide meteorological factors. These uncertainties were partially offset by the calculation of a site-specific particulate emission factor (PEF) using defined site characteristics and assumptions provided in EPA's Soil Screening Guidance (EPA, 1996c). The effect of the uncertainties using the fugitive dust model is not expected to be significant, because carcinogenic and noncarcinogenic risks estimated using the fugitive dust model were several orders of magnitude below levels of concern in the media of interest.

There is uncertainty in whether the risk assessment modeling of exposure for a construction worker to volatile airborne emissions from pooled groundwater within an excavation is sufficiently representative and protective for all types of future construction activities. This RI report estimated risks to the construction worker (non-cancer risks in Section 7.6.4.3 and cancer risks in Section 7.6.5.3) and indicated no adverse impacts were expected, while the model calculations were performed in accordance with the approved work plan, which referenced ASTM Guidance (Designation E 1739–95).

The ASTM model assumes a volatilization process consistent with conditions representative of a fairly wide and deep type of excavation (such as a basement) where pooled groundwater would occur at the bottom and wind speeds would not be greatly attenuated compared to more stagnant wind conditions that would occur within a more narrow trench-style excavation, similar to those where utility work is conducted. An alternative model was developed by DEQ, which is more conservative than the ASTM model for VOC vapor exposures to utility workers within a narrow trench.

To investigate the uncertainty in whether the ASTM modeling results were adequately protective for a future utility worker in a trench, the DEQ spreadsheet trench exposure model was run and results are provided in Appendix I, part 2. The groundwater EPCs for contaminants were input into DEQ's VRP Table

3.7, and the output modeled air concentrations were converted to units of pg/m3 to facilitate later calculation of risks. The exposure assumptions for the DEQ model were a trench width of 3 feet, length of 8 feet, and depth of 15 feet, with a depth from ground surface to groundwater of 21 feet. Exposure assumptions specific to the utility worker are presented in Appendix I, Part 2, including an exposure time of 8 hours per day, frequency of 20 days per year, and duration of 1 year, with a breathing rate of 3.3 m^3/hr. The associated cancer and non-cancer risks are presented in tables in Appendix I, Part 2, and the estimated risks to workers in a trench were below target risk levels, with cancer risks in the 10^{-9} range and the total HI in the 10^{-2} range. Therefore, no adverse effects are expected for future construction workers exposed to vapor emissions during either basement excavation activities or utility trench work at the WOD site.

The model for dermal exposure to soil assumes that only a very thin, constant thickness layer of soil is available for contaminant transfer to the stratum corneum and that a constant amount of contaminant, proportional to the soil concentration, will be absorbed per unit area of skin and per exposure event. However, adherence to skin varies with such factors as particle size, soil type, and organic carbon content. As estimated by EPA (1992f), the absorbed dermal dose could vary by as much as a factor of 50 from the model estimates, even assuming that activity patterns lead to the exposure duration applied in the experimental trials used to develop absorption factors. Because of the lack of reliable data regarding dermal absorption factors, the risk assessment provides default soil absorption factors for all substances except chemicals for which well-documented absorption factors are available (arsenic, PCBs, and PAHs). Even so, considerable uncertainty exists with the accuracy of estimates applied for these substances.

The chemical-specific parameters such as Koc were literature-derived values that are measured under conditions that may or may not be representative of on-site conditions. Parameters such as vapor pressure and solubility were not always obtainable at the desired temperature. Parameters such as the Kd for metals are strongly influenced by other factors such as the chemical form of the metal, the soil type, and pH.

Prediction of absorption rates for lipophilic compounds is difficult due to, among other reasons, the possibility of a second absorption pathway that depends on the lipid content of the stratum corneum at the application site. Experimental determination of absorption rates indicates that interspecies differences are considerable, which, along with other variability's related to condition and age of skin, differences in lag time, and site of application effects, yields appreciable uncertainty in estimated dermal exposures by using published chemical-specific permeation functions. In addition, literature data indicate a variation by as much as a factor of 300 in chemical absorption rates for skin in different anatomical areas of the body. It should also be noted that children generally have greater absorption rates than adults and their activity patterns often result in greater soil-to-skin adherence factors.

Uncertainties exist in the exposure model for the inhalation of volatiles during showering such as chemical-specific rates of volatilization, droplet size, and droplet residence time in the shower. Most of the inputs into the models were considered conservative; therefore, the output may overestimate the exposure for this route. While the Foster and Chrostowski shower model estimates were not constrained by Henry's Law principles, estimated vapor concentrations in the shower relative to concentrations in the water were relatively low using the input concentrations obtained from WOD Site groundwater and do not approach or surpass the Henry's Law equilibrium partition coefficient for any COPC modeled.

Uncertainties associated with the lack of groundwater modeling at the site include the assumption that current conditions are indicative of future concentrations of contaminants. Contaminants may increase (due to migration, sediment loading, or chemical transformation) or decrease (due to migration or transformation) over time and vary from area to area. Soil-to-groundwater pathway screening was conducted (see Section 6.4.1) to determine if any substances might be present at levels sufficient to leach into groundwater. This analysis indicated that no substances are anticipated to leach from soil to produce noteworthy groundwater concentrations in the future.

Exposure assumptions can add uncertainty into the risk assessment process based on input values selected for each exposure route. For example, not all people weigh 70 kilograms, drink 2 liters of water per day, and live at the same residence for 30 years. The rationale for each assumption was provided in each table of input parameters. Receptor characteristics, such as age and body weight, were based on published values. Conservative values (based on reasonable maximum exposure data or professional judgment) were used in combination with average values. The rate of incidental ingestion of soil is difficult to predict and depends upon activity patterns and personal habits. A default rate of ingestion of 50 mg soil per day was assumed for the industrial worked at the WOD. Recent changes in the EPA Region 3's risk assessment screening background information memorandum have adopted a new 100 mg/day worker ingestion rate as an outdoor worker exposure assumption for screening of potential COPCs. Although the EPA Region 3 website does not expand this recommendation into explicit guidance for use in quantitative risk assessments, it is relevant that the WOD risk assessment assumed activity patterns for industrial workers including outdoor groundskeepers. At the WOD, increasing the soil ingestion rate by a factor of two would be considered within a plausible range of exposure assumptions for the industrial receptors. Applying this change to the risk assessment would double the industrial worker's soil ingestion risks, but the net result would be that risks would still fall within the acceptable risk range.

7.7.3 Uncertainties Associated With Toxicity Assessment

7.7.3.1 RfDs and SFs

There is uncertainty associated with the RfDs and SFs. The uncertainty results from the extrapolation of animal data to humans, the extrapolation of carcinogenic effects from the laboratory high-dose to the environmental low-dose scenarios, and interspecies and intraspecies variations in toxicological endpoints caused by chemical exposure. The use of EPA RfD values is generally considered to be conservative because the doses are based on no-effect or lowest-observed-effect levels and then further reduced with uncertainty factors to increase the margin of safety by a factor in the neighborhood of 10 to 1,000 fold.

There are uncertainties regarding nonthreshold (carcinogenic) effects extrapolation, from the high doses administered to laboratory animals to the low doses received under more common human exposure scenarios. Uncertainties due to short-time toxicological study predictions of long-term effects are also present. Additionally, there is considerable interspecies variation in toxicological endpoints used in characterizing potential health effects resulting from exposure to a chemical, and there is considerable variability in sensitivity among individuals of any particular species.

The RfDs and SFs of some chemicals have not been established, and therefore toxicity could not be quantitatively assessed. In most cases, where RfDs were unavailable for carcinogens, the carcinogenic risk is considered to be much more significant since carcinogenic effects usually occur at much lower doses.

The uncertainty associated with the dermal exposure is high because of the derivation of the dermal slope factor and reference dose. The dermal toxicity factors are based on default oral absorption factors. This can result in an overestimation of the toxicity factors. In general, dermal exposures at WOD Site did not drive the carcinogenic or noncarcinogenic risks; therefore, the effects of this uncertainty are expected to be minimal.

As discussed in Section 7.5, established RfDs have an inherent amount of uncertainty. Uncertainty factors for RfDs used in this risk assessment are presented in Tables 7.29 through 7.32. Some chemical specific uncertainties should be noted as follows:

Although the accepted basis for evaluating risk associated with exposure to arsenic is to assume it is a carcinogen, there is uncertainty whether carcinogenic effects are the primary health effects expected to be manifested upon exposure to arsenic. There is some scientific information to indicate that humans are capable of metabolizing arsenic to expedite its elimination from the body (ATSDR, 2000). (Specifically,

the body methylates the arsenic to form monomethyl arsenic and dimethyl arsenic.) There is a limited capacity for the body to metabolize methylate arsenic, but this limit is generally reached when the body's intake of arsenic approximately exceeds 500 µg/day. Generally, concentrations of arsenic at the areas and media of interest at WOD Site would be expected to correspond to levels that are well within the body's ability to metabolize arsenic. On the other hand, arsenic has been associated with a variety of cancers in epidemiological studies. This adds to the uncertainty regarding carcinogenic risks associated with arsenic exposure.

In nature, chromium (III) predominates over chromium (VI) (Langård and Norseth 1986). Little chromium (VI) exists in biological materials, except shortly after exposure, because reduction to chromium (III) occurs rapidly. Hexavalent chromium can also be transformed to trivalent chromium. However, hexavalent chromium is more soluble, and chromium in water samples is often found to be hexavalent. A usable database of chromium speciation data was not available for the WOD site; therefore, in performing RBC screening it was conservatively assumed that chromium is present in the hexavalent form. Chromium was selected as a COPC in groundwater, so associated risks may be overestimated if chromium (III) is present instead of chromium (VI).

Incidental ingestion of iron exceeded EPA's hazard quotient threshold of 1.0 under certain exposure pathways and receptors. Currently, no toxicity values for iron are published in (IRIS) or in (HEAST). The oral reference dose used to evaluate exposures to iron was obtained from the current EPA Region 3 RBC tables. This value is based on an allowable daily intake and not on an adverse effect level. In addition, iron is considered an essential nutrient. Consequently, iron may not warrant serious health concerns.

To minimize uncertainty, toxicity factors (SFs and RfDs) should be obtained only from published sources (IRIS, HEAST, and NCEA) because these sources represent peer-reviewed and nationally accepted estimates. However, in this risk assessment, the SF for tetrachloroethene was adopted from an outside source, California's Environmental Protection Agency (CAL-EPA). Although the toxicity value utilized was recommended in the June 17, 2003 update to EPA's risk-based concentration table, CAL-EPA is not generally considered a nationally accepted source for toxicity values. Since the CAL-EPA SF of 0.54 is 27-fold greater than the value previously accepted by EPA (0.02), this contributes substantial uncertainty to the cancer risk estimates generated for tetrachloroethene.

7.7.4 Uncertainties Associated with Risk Characterization

Major uncertainties associated with risk characterization are listed below.

- ICRs and HIs are summed for all potential COPCs and for all applicable routes of exposure. Summing the risks implies that no antagonistic or synergistic effects exist between chemicals. It also assumes that similar mechanisms of action and metabolism are prevalent. Therefore, the use of this approach may either underestimate or overestimate the risks, depending on the chemical-specific interactions, which cannot be predicted. The direction of the uncertainty cannot be defined, but the methodology used is based on current EPA guidance.

- The chemicals of concern (COCs) and their associated cleanup levels for remedial actions are focused only on site-related substances; however, there is a conceivable potential for adverse effects not only from exposure to site-related substances (i.e., COPCs) but also from risks due to non-site-related background substances. Aluminum, arsenic, barium, cadmium, chromium, copper, iron, lead, manganese, thallium, vanadium, and zinc concentrations were demonstrated to be statistically not greater than background and were therefore eliminated as COPCs from soil*. In addition, statistical tests revealed that aluminum, arsenic, iron, manganese, and vanadium concentrations were not greater than background in surface soil. A qualitative screening assessment of risks from exposures to the background levels of metals at the WOD Site can be performed by comparing their WOD Site soil EPCs (found in Appendix G, distributional analysis tables) versus the unadjusted RBCs, which are based upon a 10^{-6} cancer risk or a HQ of 1.0. In WOD surface soil and soil*, these metals, except for arsenic, displayed EPCs that were each less than one-half their respective RBCs at a HQ of 1.0, while the EPCs for arsenic were less than the RBC at a cancer risk level of 10^{-5}. This indicates that the potential for adverse effects from these background metals is negligible for ingestion exposures, although there is need for considering uncertainty regarding risk from dermal contact with soil because RBCs do not account for this pathway of exposure. For the exposure scenarios described in Section 7.4, dermal contact with relatively dry soil having low soil-to-skin adherence factors (see values presented on RAGS D Table 4s) would yield dermal contact risks for these background metals that are less than corresponding ingestion risks for the same receptors under the same conditions of frequency and duration of exposure. Therefore, in soils at the WOD Site, there is a low likelihood of any significant contributions from background metals concentrations to overall receptor risks.

- Risks to any individual may also be overestimated by summing multiple assumed exposure pathway risks for any single receptor. Although every effort was made to develop reasonable scenarios, not all individual receptors may be exposed via all pathways considered.

- The IEUBK and the adult lead model account for the multimedia nature of lead exposure, incorporates absorption and pharmacokinetic information, and allows the risk manager to consider the potential distributions of exposure and risk likely to occur at a site (the model goes beyond providing a single point estimate output). Although uncertainties are associated with blood-lead

modeling using these models, the uncertainties are considered lower than those that conceivably would result from similar lead evaluations performed using a traditional toxicity slope-based approach. Important uncertainties and limitations in the use of the IEUBK model are listed below.

- The IEUBK model is predictive of blood lead for residential children in the range of 6 months to 7 years of age, which typically is considered to be a more sensitive subpopulation than adults. The model does not apply to adults in either residential or industrial settings. For this reason, the adult lead model could also be considered, which considers the most sensitive adult subpopulation, a pregnant worker. However, lead was not selected as a COPC in any medium to which industrial workers would be potentially exposed.

- Blood-lead variability is characterized by a single number, the geometric standard deviation, which is set to a default value of 1.6 in the IEUBK model and 1.8 in the adult lead model. This value represents the aggregate uncertainty in all sources of population variability, including biological, uptake, exposure, sampling, and analytical components.

- Child blood-lead level predictions obtained using the IEUBK model reflect only the contributions of sources entered into the model and do not take into account any existing body burden that may be the result of prior exposures or any exposures that may have taken place at alternate locations away from the household or neighborhood level, such as parks or daycare centers.

7.8 SUMMARY AND CONCLUSIONS

Site-specific carcinogenic and noncarcinogenic risks were estimated for potential receptors at the WOD site. Potential receptor scenarios included current and future industrial workers, future construction workers, and hypothetical future residential users. No change in the future use of the site is likely as it is near an active runway that is an important part of the future facility plan for the installation.

The future residential scenario is highly unlikely not only due to the location of the site but it also assumes the use of the shallow aquifer for domestic purposes. Public water is available at the site and use of the shallow aquifer is highly unlikely. The shallow aquifer is not as productive as the lower aquifer present in the area and the use of the shallow aquifer is restricted by the state. As discussed in Section 2.3.4, groundwater use in the area is controlled and allocated through a permitting program administered by the state under the Virginia Groundwater Management Act. The site area is located within a Critical Groundwater Area as designated by the Commonwealth of Virginia and the use of the shallow aquifer is restricted through the issuance of use permits. The SWCB administers the permit program and consults with the Department of Health and local commissions in evaluating permit requests. The

Accomack/Northampton County Water Supply Committee has been established as a local commission to work with and advise the state in evaluating permit applications. This committee meets regularly and has established local restrictions on additional withdrawals of groundwater from the shallow aquifer and require monitoring programs to ensure that existing groundwater users are not impacted by new deep aquifer withdrawals.

7.8.1 Noncarcinogenic Risks

Noncarcinogenic risks did not exceed an HI of 1.0 for any target organ group for receptors potentially exposed to surface soils or total soils (soils*), including the industrial worker, construction worker, residential child, or residential adult. Similarly, noncarcinogenic risks did not exceed an HI of 1.0 for any target organic group for the construction worker potentially exposed to groundwater.

Target organ group HIs greater than 1.0 were estimated for potential domestic use of the shallow groundwater by hypothetical future child and adult residents. The risk drivers include arsenic, iron, manganese, aluminum, chromium, 4-methylphenol, xylene, 1,2,4-trimethylbenzene, and naphthalene.

7.8.2 Carcinogenic Risks

Carcinogenic risks were within or less than the acceptable risk range (1×10^{-4} to 1×10^{-6}) for the current and future industrial worker, future construction worker, future child resident, future adult resident, and future lifetime resident potential exposure to surface soils and total soils (soils*)

Carcinogenic risks associated with potential future construction workers exposed to groundwater were less than the acceptable risk range. The risk for hypothetical future child and adult residents exposed to groundwater for domestic purposes, slightly exceeded the acceptable risk range (1.9×10^{-4} and 2.4×10^{-4}, respectively), which resulted in an unacceptable lifetime estimated carcinogenic risk. The primary risk drivers were arsenic, benzene, tetrachloroethene, chloroform, and bis(2-ethylhexyl) phthalate. The most significant risks were associated with the potential ingestion of untreated shallow groundwater and the arsenic levels detected in the groundwater. Risks associated with arsenic were the only risks greater than 1×10^{-4}. Eliminating arsenic, results in an overall risk within the acceptable risk range.

In conclusion, unacceptable carcinogenic and noncarcinogenic risks were associated with only hypothetical future residential use of groundwater.

8.0 ECOLOGICAL RISK ASSESSMENT (ERA)

As described the work plan (TtNUS, 2003a), surface soil analytical data collected under this Supplemental RI (including the soil/sediment samples collected in the marsh area) first were combined with the existing 2001 RI data set and then compared to the existing data set. This comparison was conducted to determine if an Ecological Risk Assessment (ERA) needed to be conducted for the surface soil data, since an ERA was conducted on the existing data set. Regardless of the results of this comparison, however, the surface soil samples collected in the marsh area were compared to sediment criteria in this ERA to conservatively evaluate potential risks to aquatic receptors should the soil/sediment from the marsh area be transported to a water body (i.e., Little Mosquito Creek).

Table 8.1 presents the historical (2001 RI), new (Supplemental RI), and combined data sets. Several VOCs were detected in the new data set whereas no VOCs were detected in the historical surface soil samples. Also, a few SVOCs were detected in the new samples but were not detected in the historical samples. The SVOCs that were detected in the historical samples were generally detected at greater concentrations than the current samples. In general, the metals were detected at similar concentrations in the new and historical samples. However, cadmium, mercury, and thallium were detected in the new samples but were not detected in the historical samples. Therefore, although the concentrations in the new samples were similar to those in the historical samples for the detected chemicals, several chemicals were detected in the new samples that were not detected in the historical samples. Because those additional chemicals were not evaluated in the previous ERA, it was determined that an ERA should be conducted to evaluate risks to soil receptors as part of this Supplemental RI.

The goal of this Screening-Level Ecological Risk Assessment (SERA) is to determine whether adverse ecological impacts are present as a result of exposure to chemicals released to the environment through historical activities at the Waste Oil Dump (WOD). This SERA contains information that will enable scientists and managers to conclude either that ecological risks at the site are most likely negligible, or that further information is necessary to evaluate potential ecological risks at the site.

The Ecological Risk Assessment (ERA) methodology used at the site follows the guidance presented in the following guidance documents:

- Final Guidelines for Ecological Risk Assessment [United States Environmental Protection Agency (USEPA), 1998].

- Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments (USEPA, 1997a).

- Navy Policy for Conducting Ecological Risk Assessments [Department of Navy (DON), 1999].

Figure 8.1 presents the Ecological Risk Assessment Tiered Approach.

This ERA consists of Steps 1, 2, and 3a of the eight steps required by the above mentioned guidance. The first two steps are the SERA. In the SERA, conservative exposure estimates are compared to screening levels and threshold toxicity values. The SERA includes the following considerations:

- Problem formulation
- Ecological effects evaluation
- Exposure estimate
- Risk calculation

Step 3a is the first step of the baseline ecological risk assessment (BERA) and consists of refining the conservative exposure assumptions following Steps 1 and 2. Step 3a is meant to focus the ERA process on the chemicals of greatest concern at a site and is a valuable step to be used in risk management decision making. Steps 3b through 7 may be conducted if additional evaluations or investigations are warranted after step 3a. Step 8, Risk Management, is incorporated throughout the ERA process and includes the cooperation with the VADEQ and resource trustees.

8.1 PROBLEM FORMULATION

Problem formulation is the first phase of an ERA and discusses the goals, breadth, and focus of the assessment. It includes general descriptions of the WOD with emphasis on the habitats and ecological receptors present. This phase also involves characterization of site-related chemicals, chemical sources, migration routes, and an evaluation of routes of chemical exposure. The assessment and measurement endpoints to be evaluated are also selected. Finally, a conceptual model is developed that describes how chemicals associated with the site in question may come into contact with ecological receptors. The following sections provide more detailed descriptions of the steps completed as a part of the problem formulation.

8.1.1 Environmental Setting

The Environmental Resources Document (Occu-Health, Inc., 1999) and the Work Plan (TtNUS, Inc., 2003) present detailed descriptions of the terrestrial and wetland habitats present at the WFF and the WOD. The following sections summarize those descriptions.

WFF is comprised of the Main Land (ML), Main Base (MB), and Wallops Island (WI). The vegetative zones on the ML and MB are diverse and extensive, and proceed east to west from marsh to thicket to forest (Occu-Health, Inc., 1999). Habitats within WFF, including ML, MB, and WI, include dune systems, island forest, salt marsh, upland grasslands, and forest, providing food, shelter, breeding, and nesting grounds to a diverse community of species.

The WOD is located within the MB area. Although a survey of terrestrial species present on the WFF has never been conducted, documentation is available for Assateague Island. Assateague Island neighbors WFF, has similar habitats and settings, and is believed to contain many of the same species. Surveys conducted at Assateague Island have revealed the presence of mammals including white-tailed deer (*Odocoileus virginianus*), meadow voles (*Microtus pensylvanicus*), raccoons (*Procyon lotor*), and grey squirrels (*Sciurus carolinensis*); reptiles/amphibians including fowler's toad (*Bufo woodhoussei*), green tree frog (*Hyla cinerea*), black rat snake (*Elapha obsoleta*), hognose snake (*Heterodon platyrhinos*), and box turtle *(Terrapene caolina*); birds including shorebirds such as sanderling (*Calidris alba*), short-billed dowitcher (*Limnodromus griseus*), and various species of tern (*Sterna sp.*) and gulls (*Larus sp.*), songbirds and other avian species such as mockingbirds (*Mimus sp.*), robins (*Turdus migratorius*), and starlings (*Sturnus vulgaris*); and plants including common terrestrial vegetation and wetland species.

Waste Oil Dump

The WOD is located in the northeast quadrant of the MB and is about 160 feet north of the end of Runway 17-35 (Figure 4.1). It extends in a northerly direction over a peninsula-like feature toward Little Mosquito Creek. The northern, eastern, and western boundaries of the site are steep slopes where surface runoff flows into low-lying marshes that border an unnamed tributary to Little Mosquito Creek. The WOD is heavily vegetated with grasses, shrubs, and saplings.

There are no surface water bodies within or immediately adjacent to the WOD. Most of the WOD is relatively flat, with the majority of precipitation expected to infiltrate into the ground. The northern, eastern, and western boundaries of the site are formed by steep slopes that direct non-infiltrated surface runoff into low-lying marshes that border an unnamed tributary to Little Mosquito Creek and Little Mosquito Creek. The closest stream to the WOD is the unnamed tributary to Little Mosquito Creek that is located about 160 feet to the west of the WOD. This creek flows adjacent to and between Sites 14 and 15, and carries drainage and permitted discharges from the MB to Little Mosquito Creek. Approximately 300 feet of marshland to the north and east separate the WOD from Little Mosquito Creek. The unnamed tributary and Little Mosquito Creek are being studied under the RI for Sites 14 and 15 which have a greater potential direct link to these surface water bodies. The Site 14 and 15 RI includes a BERA as part of its scope.

8.1.2 Potential Sources of Contamination/Stressor Characteristics

The WOD was reportedly used for the disposal of waste oils, and possibly solvents. This included the excess waste oil from the fire training activities for a period from the 1940's through the 1950's (Versar, Inc., 2001). Records of the types and quantities of materials disposed at the site and the duration of this activity were not available.

Section 5.0 of this document describes in detail the potential sources and the nature and extent of contamination at the WOD. Detections of VOCs, SVOCs, PCBs, and metals have been identified as chemicals potentially present at elevated levels at the WOD. Physical and chemical characteristics of contaminants may affect their mobility, transport, and bioavailability in the environment, including organic carbon partition coefficients, pH, octanol water partition coefficients, etc. Appendix H.1 presents toxicity profiles for the chemical constituents detected in the surface soil/sediment samples at the site and are qualitatively used to help evaluate ecological risks.

8.1.3 Potential Exposure Pathways

Based on historical site operations, the primary source of chemicals originated from the disposal of waste oil and solvents in the soil at the site. Terrestrial receptors may be exposed to chemicals in the surface soil. The contaminants could migrate through the soil into the groundwater and eventually into the sediment or soil of the surrounding marshland. Also, over time, soil erosion could lead to overland runoff down the slopes into the sediment of the surrounding marshland, and chemicals in the soil can enter the air through wind erosion and/or dust.

8.1.3.1 Surface Soil

Several groups of terrestrial ecological receptors can be exposed to chemicals in the surface soil. Invertebrates, such as earthworms, are exposed to chemicals as they move through the soil and ingest soil particles while searching for food. Plants are exposed to chemicals via direct contact as chemicals are absorbed through the roots, which may then translocate to different parts of the plants (i.e., leaves, seeds).

Small mammals, birds, reptiles, and amphibians may be exposed to chemicals in the soil via several exposure routes. They may be exposed by direct contact as they search for food or burrow into the soil. Exposure of terrestrial wildlife to chemicals in the soil via dermal contact is unlikely to represent a major exposure pathway because fur, feathers, and chitinous exoskeletons are expected to minimize transfer of chemicals across dermal tissue. Most small wildlife receptors are likely to have their greatest exposure to

chemicals in the soil via incidental ingestion of soil, and ingestion of plants and/or invertebrates that have accumulated chemicals from the soil.

Larger, predatory species, such as the red fox and red-tailed hawk, can be exposed (indirectly) to site chemicals in the soil by ingesting small mammals that have accumulated chemicals from the soil and food items.

8.1.3.2 Sediment

Ecological receptors can be exposed to chemicals in the sediment. Benthic invertebrates, amphibians, and reptiles can be exposed to sediment contamination through direct contact and incidental ingestion of contaminated sediment. Fish may also be exposed to sediment (and floodplain soil) contaminants during flooding events but their exposure will be much lower than the exposure for benthic invertebrates. Terrestrial wildlife may also be exposed to sediment contamination, although to a lesser degree, by direct contact and incidental sediment ingestion.

8.1.4 Endpoints

8.1.4.1 Assessment Endpoints

Assessment endpoints are an explicit expression of the environmental value that is to be protected (USEPA, 1997a). The selection of these endpoints is based on the habitats present, the migration pathways of chemicals, and the routes that chemicals may take to enter receptors.

The habitat within and adjacent to the WOD is diverse consisting of forested areas, grassy areas, and marshlands. For this ERA, the assessment endpoints include the protection of the following groups of receptors from a reduction in growth, survival, and/or reproduction caused by site-related chemicals:

- Soil invertebrates
- Terrestrial vegetation
- Insectivorous birds and mammals
- Herbivorous birds and mammals
- Benthic invertebrates
- Reptiles

The following paragraphs discuss why the above assessment endpoints were selected for this ERA.

Soil Invertebrates - Soil invertebrates include earthworms, the juvenile life stages of many insects, and other small organisms that directly inhabit the surface soil. These organisms are expected to be present in the soil in terrestrial habitats at the site. Soil invertebrates promote plant growth by aiding in the formation of soil and through redistribution and decomposition of organic matter. Soil invertebrates also serve as a food source for many mammals and birds. Contaminants can bioaccumulate from the soil into the tissue of soil invertebrates used as a food source by mammals and birds.

Terrestrial Vegetation - Terrestrial vegetation at the site consists of conifers, bushes, and tall grasses. These plants serve as a source of food and shelter for many organisms and help prevent soil erosion and excessive surface runoff. Plants can also bioaccumulate some chemical contaminants from the soil that can then be transferred to organisms that feed on plant tissue.

Insectivorous Birds and Mammals - Insectivorous birds and mammals (animals that consume insects and other invertebrates) present at the WOD are considered first-level carnivores, and they serve as a food source for higher trophic-level carnivores. Insectivorous birds and mammals may accumulate contaminants that are present in the food items they consume.

Herbivorous Birds and Mammals - Herbivorous birds and mammals (animals that consume only plant tissue) forage at the site. Their role in the community is essential because, without them, higher trophic levels could not exist. They may accumulate contaminants that are present in the plants they consume.

Benthic Invertebrates - Benthic invertebrates are similar to soil invertebrates in that they serve as a food source for higher trophic-level organisms (i.e., fish, amphibians, and birds). They can also accumulate some contaminants that can then be transferred to the higher trophic-level organisms when consumed.

Reptiles-Reptiles are present in the terrestrial areas at the site. These species feed primarily on invertebrates, plants, and small mammals. Reptiles are exposed to and can accumulate contaminants from the food items they consume or from the surface soil in which they live.

As indicated in USEPA (1997a), “it is not practical or possible to directly evaluate risks to all of the individual components of the ecosystem at a site. Instead, assessment endpoints focus the risk assessment on particular components of the ecosystem that could be adversely affected by contaminants from the site.” Therefore, the ERA focused on the endpoints that tend to yield the highest risks, which will account for endpoints that have lower risks.

Piscivorous mammals and birds were not selected as assessment endpoints because a complete exposure pathway from the soil to surface water where fish would be contaminated occurs infrequently.

Although sediment samples were collected in the marsh area surrounding the WOD, there was no standing water associated with the sediment samples. The sediment samples were, however, included in the soil data set to evaluate risks to terrestrial wildlife through the food chain. It is possible that fish may be exposed to chemicals in the soil/sediment at the base of the slope on an infrequent basis during flooding conditions because the unnamed tributary to Little Mosquito Creek is within 25 feet of the base of the slope. Because their exposure is infrequent, they will accumulate less contaminants from the soil/sediment than invertebrates. Therefore, fish were not selected as an endpoint because soil invertebrates have a much greater exposure to contaminants than fish and the potential risks to fish are being accounted for by evaluating risks to invertebrates. Similarly, piscivorous birds were not selected as an assessment endpoint for this ERA because shrews that consume soil invertebrates will have a much greater exposure to site contaminants than piscivorous birds consuming fish that are infrequently exposed to the site contaminants. Large carnivorous mammals and birds (e.g., red fox and red-tailed hawk) were not selected as assessment endpoints because the greatest exposure to site contaminants is expected to occur to small mammals and birds that ingest invertebrates and/or plants. That is principally because the site is small (approximately 3.5 to 4 acres) compared to the typical home range of carnivorous mammals and birds (several hundred acres). Omnivores were not selected as assessment endpoints because exposure to contaminants in plants is greatest for herbivores and exposure to contaminants in animals is greatest for insectivores. Therefore, risks to omnivores are accounted for by evaluating risks to herbivores and insectivores. Risks to large carnivorous and omnivorous mammals and birds are evaluated in the uncertainty section of this ERA. In addition, although amphibians may be present at the site they were not selected as an assessment endpoint because no methods are available to quantitatively evaluate risks to amphibians.

8.1.4.2 Measurement Endpoints

Measurement endpoints are estimates of biological impacts (i.e., mortality, growth and reproduction) that are used to evaluate the assessment endpoints. The following measures of effects were used to evaluate the assessment endpoints in this ERA.

- Mortality, growth, and/or reproduction of plants, soil invertebrates, and benthic invertebrates were evaluated by comparing chemical concentrations in surface soil and sediment to screening values designed to be protective of ecological receptors.

- Mortality, reproduction, and/or developmental effects of birds and mammals were evaluated by comparing estimated ingested doses of contaminants in plants, invertebrates, and surface soil to no-observed-adverse-effects-levels (NOAELs) and lowest-observed-adverse-effects-levels (LOAELs).

- Reptiles were evaluated by evaluating risks to birds and mammals because no methods are available to quantitatively evaluate risks to reptiles.

8.1.4.3 Selection of Receptor Species

Many receptors such as invertebrates and plants are adequately described in general categories such as invertebrates and vegetation. This is due to the nature of the threshold values and effects values that are typically used to characterize risk for such organisms. For vertebrate receptors, selection of particular species may be required so that intake through eating, drinking, and other routes can be estimated.

Ingestion is the primary route of exposure for most mammals and birds. The selection of species used to represent the receptor groups identified in Section 8.1.4.1 was based on considerations of their preferred habitat, body size, sensitivity, home range, abundance, commercial or sport utilization, legal status, and functional role (e.g., predators). To be conservative, chosen representative species have small home ranges. The availability of exposure parameters such as body mass, feeding rate, and drinking rate may also be a factor in selecting surrogate species. The following surrogate species were used for the food chain modeling, which is discussed in Section 8.3:

- Insectivorous mammal-Short-tailed shrew
- Insectivorous bird-American robin
- Herbivorous mammal-Meadow vole
- Herbivorous bird-Bobwhite quail

Receptor profiles for the above species are included in Appendix H.2.

8.1.5 Conceptual Site Model

A CSM in ERA problem formulation is a written description of predicted relationships between ecological entities and the stressors to which they may be exposed (USEPA, 1998). The CSM consists of two primary components: predicted relationships among stressor, exposure, and assessment endpoint response and a diagram that illustrates the relationships (USEPA, 1998). Figure 8.2 is a pictorial presentation of these relationships. At the WOD, the source of the chemicals is the disposal of waste oils and solvents on the ground. Therefore, the immediate exposure medium is the surface soil. Terrestrial plants, invertebrates, and vertebrates are exposed to the surface soil by direct contact, ingestion of soil and other food items. Some of the contamination may have migrated to groundwater, or have been transported to the marsh sediment via overland runoff. Eventually, some of the contamination may make its way to be the tributary of Little Mosquito Creek, and eventually to Little Mosquito Creek. Aquatic

receptors may be exposed to the chemicals after the chemicals are transported to aquatic environments. Additionally, site soil contaminants are transported to air via wind erosion and emission of VOCs. Terrestrial vertebrates are exposed to chemicals found in the air via inhalation. Although this pathway is possible, it is not the most significant pathway and is not evaluated in this ERA.

8.2 ECOLOGICAL EFFECTS DATA

The preliminary ecological effects evaluation is an investigation of the relationship between the exposure to a chemical and the potential for adverse effects resulting from exposure. In this step, conservative screening levels for toxicity of the chemicals to ecological receptors are compiled.

8.2.1 Terrestrial Plants/Invertebrates and Benthic Invertebrates

Risks to terrestrial plants/invertebrates and benthic invertebrates resulting from exposure to chemicals were evaluated by comparing the chemical concentrations in the surface soil and sediment to screening levels for those media (see Tables 8.2 and 8.3, respectively). The Region 3 BTAG criteria (USEPA, 1995) were used for this ERA because they were developed specifically for use within USEPA Region 3 to evaluate potential risks to ecological receptors. The Region 3 BTAG criteria are considered to be conservative values protective of the most sensitive organisms. These toxicity values are expressed in units of concentration because the media of concern are in intimate contact (direct exposure) with terrestrial plants/invertebrates and aquatic receptors. These criteria were supplemented with other values when BTAG criteria were not available.

8.2.2 Terrestrial Food Chain Modeling

The Region 3 BTAG criteria are not designed to evaluate risks to terrestrial wildlife through the ingestion of soil, sediment, plants, and/or invertebrates. Therefore, risks to terrestrial receptors for exposure to chemicals found in the surface soil were determined by estimating the Chronic Daily Intake (CDI) and comparing the CDI to Toxicity Reference Values (TRVs) representing acceptable daily doses in mg/kg-day. The TRVs were developed from NOAELs and LOAELs obtained from wildlife studies presented in Oak Ridge National Laboratory (ORNL) Toxicological Benchmarks for Wildlife: 1996 Revision (Sample et al., 1996) and supplemented with other toxicity information when necessary.

Appendix H.3 presents the TRVs for the mammals and birds that were used in the ERA and the sources of the TRVs. If a subchronic study was used to develop the TRV, the final value was multiplied by a factor of 0.1 to account for uncertainty between subchronic and chronic effects. Also, if only a LOAEL study was available, then the LOAEL was multiplied by a factor of 0.1 to obtain the NOAEL TRV.

8.3 EXPOSURE CHARACTERIZATION

In order to determine if a chemical has the potential to cause a risk to an ecological receptor, a chemical concentration or chemical dose was compared to the screening levels/TRVs. These chemical concentrations/doses are termed exposure point concentrations (EPCs). The following paragraphs indicate the EPCs that were used for each set of ecological receptors.

8.3.1 Terrestrial Plants and Invertebrates

Terrestrial soil invertebrates and plants can be exposed to contaminants in the surface soil through direct contact and/or ingestion. As indicated in Section 8.2.1, the screening values for these receptors are in units of chemical concentration in each medium. Therefore, the EPCs used for these receptors were the maximum chemical concentrations in each medium.

8.3.2 Aquatic Receptors

Benthic invertebrates can be exposed to contaminants in the sediment through direct contact and/or ingestion. As indicated in Section 8.2.1, the screening values for these receptors are in units of chemical concentration in each medium. Therefore, the EPCs used for these receptors were the maximum chemical concentrations in each medium.

8.3.3 Terrestrial Wildlife

The exposures to chemicals for mammals and birds are more complex than the exposures for plants and soil invertebrates and require evaluation of bioaccumulation of chemicals in various food items. Therefore, the EPCs for terrestrial wildlife were estimated in mg/kg-day using exposure dose equations. EPCs for terrestrial wildlife were only calculated for chemicals identified by EPA as bioaccumulative (USEPA, 2000).

Total exposure of terrestrial wildlife to chemicals of potential concern (COPCs) in soil (and associated food items such as plants and invertebrates) were determined for the surrogate wildlife species listed in Section 8.1.4.3 using the following equation:

$$CDI = \frac{[(Cf * IR) + (Cs * Is)] * H}{BW}$$

Where:

CDI	=	Chronic daily intake (mg/kg-day)
Cf	=	Chemical concentration in food - (see discussion below)
Cs	=	Contaminant concentration in surface soil (mg/kg)
IR	=	Food ingestion rate (kg/day)
Is	=	Incidental surface soil ingestion rate (kg/day)
H	=	Portion of food intake from the contaminated area (unitless)
BW	=	Body weight (kg)

Contaminant concentrations in food items were calculated as follows using soil to plant or invertebrate bioaccumulation factors (BAFs) from published sources.

$$Cf = Cs * BAF$$

Where:

Cf	=	Chemical concentration in food (mg/kg)
Cs	=	Contaminant concentration in surface soil (mg/kg)
BAF	=	Biota-soil bioaccumulation factor

Appendix H.1 presents chemical-specific dry weight BAFs that were used in this ERA. The following sources were used to obtain most of the BAFs in this ERA, additional sources used to develop BAFs for the PAHs as described in Appendix H.1:

- Plant BAFs for Organics: Toxicity and Chemical-Specific Factors Database (ORNL, 2002).

- Plant BAFs for Inorganics: Empirical Model for the Uptake of Inorganic Chemicals from Soil by Plants (ORNL, 1998).

- Soil Invertebrate BAFs: Development and Validation of Bioaccumulation Models for Earthworms (Sample et al., 1998).

The diets of the meadow vole and bobwhite quail were assumed to consist of vegetation, while the diets of the short-tailed shrew and American robin were assumed to consist of soil invertebrates (i.e., earthworms). Therefore, chemical concentrations in food items of the meadow vole and bobwhite quail were estimated by multiplying each COPC's surface soil concentration by its associated soil-to-vegetation

BAF. The chemical concentrations in food items of the short-tailed shrew and American robin were estimated by multiplying each COPC's surface soil concentration by its associated soil-to-invertebrate BAF.

The food chain model scenarios were calculated using various exposure assumptions and TRVs to present a range of risks. For selecting chemicals as COPCs, the following sets of exposure assumptions were used:

- Maximum soil concentrations
- 90^{th} percentile BAFs and biota-sediment bioaccumulation factors (BSAFs) (or maximum value if a 90^{th} percentile value was not available)
- Conservative receptor body weight and ingestion rates
- Receptors spend 100% of their time at the site

For refining the list of COPCs in Step 3a (see Section 8.5), the following set of exposure assumptions were used:

- 95% upper confidence limit (UCL) soil concentration
- Median BAFs (or average value if a median value was not available or appropriate)
- Average receptor body weight and ingestion rates
- Receptors spend 100% of their time at the site. The ecological effects quotients (EEQs) reflect this assumption; however, receptors' home ranges were qualitatively taken into account during the Step 3a evaluation.

and;

- Average soil concentration
- Median BAFs (or average value if a median value was not available or appropriate)
- Average receptor body weight and ingestion rates

- Receptors spend 100% of their time at the site. The EEQs reflect this assumption; however, receptors' home ranges were qualitatively taken into account during the Step 3a evaluation.

Appendix H.2 presents the derivation of the exposure parameters used for the surrogate species. The final exposure values that were used in the food chain model are summarized in Table 8.4. The exposure assumptions (i.e., ingestion rate, body weight) were obtained primarily from the Wildlife Exposure Factors Handbook (USEPA, 1993); other sources were used when necessary.

8.4 RISK CHARACTERIZATION

The risk characterization is the final phase of an ERA that compares exposure to ecological effects. It is at this phase that the likelihood of adverse effects occurring as a result of exposure to a stressor was evaluated. An EEQ approach was used to characterize the risk to potential terrestrial receptors. This approach characterizes the potential effects by comparing exposure concentration with the effects data.

When EEQ values exceed 1.0, it is an indication that ecological receptors are potentially at risk; additional evaluation or data may be necessary to confirm with greater certainty whether ecological receptors are actually at risk, especially since most benchmarks are developed using conservative exposure assumptions and/or studies. The EEQ value should not be construed as being probabilistic; rather, it is a numerical indicator of the extent to which an exposure point concentration exceeds or is less than a benchmark.

An EEQ for terrestrial plants and invertebrates was calculated as follows:

$$EEQ = \frac{C_{ss}}{SSSL}$$

where:

EEQ = Ecological effects quotient (unitless)

C_{ss} = Contaminant concentration in surface soil (µg/kg or mg/kg)

SSSL = Plant or invertebrate surface soil screening level (µg/kg or mg/kg)

An EEQ for aquatic receptors was calculated as follows:

$$EEQ = \frac{C_{sd}}{SdSL}$$

where:

EEQ = Ecological effects quotient (unitless)

C_{sd} = Contaminant concentration in sediment (µg/kg or mg/kg)

SdSL = Aquatic receptor sediment screening level (µg/kg or mg/kg)

The EEQ for the terrestrial wildlife model was calculated as follows:

$$EEQ = \frac{CDI}{TRV}$$

where:

EEQ = Ecological effects quotient, (unitless)
CDI = Chronic daily intake dose, (mg/kg-day)
TRV = Toxicity reference value (NOAEL or LOAEL), (mg/kg-day)

8.5 SELECTION OF CHEMICALS OF POTENTIAL CONCERN

The final part of the screening evaluation is selection of COPCs. Chemicals that are not selected as COPCs are assumed to present negligible risk to ecological receptors and are not considered for further evaluation in the ERA. Chemicals that are retained as COPCs are evaluated further in Step 3a to determine if they are carried through as chemicals of concern (COC). Ecological COPCs were initially selected by the following procedures:

- Chemicals with EEQs greater than 1.0 based on screening values were retained as COPCs for further evaluation because they have a potential to cause risk to ecological receptors.

- Chemicals with EEQs greater than 1.0 based on the food chain model using NOAELs were selected as COPCs because they have the potential to cause risks to mammals and birds.

- Chemicals without screening levels were retained as COPCs but are only evaluated qualitatively.

- Calcium, magnesium, potassium, and sodium were not retained as COPCs because they are essential nutrients that can be tolerated by living systems even at high concentrations. No evidence indicates that these chemicals are related to site operations, and they are not considered hazardous chemicals.

8.5.1 Risks to Terrestrial Invertebrates and Plants

Table 8.2 presents the selection of the chemicals retained as COPCs in surface soil. Eight VOCs and two SVOCs were retained as COPCs because no toxicity information was available for these chemicals.

Ten SVOCs (including total PAHs), Aroclor-1260, and thirteen metals were retained as COPCs because their maximum concentrations exceeded associated surface soil screening levels (SSSLs).

8.5.2 Risks to Aquatic Receptors

Table 8.3 presents the selection of chemicals retained as COPCs in sediment. Five VOCs, one SVOC, and one metal were retained as COPCs because no toxicity information was available for these chemicals. Three SVOCs [including high molecular weight (HMW) PAHs and total PAHs], Aroclor-1260, and nine metals were retained as COPCs because their maximum concentrations exceeded associated sediment screening levels (SdSLs).

8.5.3 Risks to Terrestrial Wildlife

Of the detected chemicals, eleven SVOCs (including total PAHs), Aroclor-1260, and ten metals were included in the food chain model because they are considered important bioaccumulative chemicals (USEPA, 2000). These chemicals are indicated as "BIO" on Table 8.2. Table 8.5 summarizes the results of the conservative inputs food chain modeling for the terrestrial surrogate species for the WOD. Appendix H.4 contains the calculation worksheets. After performing the food-chain modeling using maximum detected concentrations and conservative exposure parameters, the following results were found:

- Soil insectivorous receptors-Aroclor-1260 and seven metals were retained as COPCs for the short-tailed shrew because the NOAEL EEQs were greater than 1.0 in the conservative scenario food chain model (see Table 8.5). Aroclor-1260 and six metals were retained as COPCs for the American robin because the NOAEL EEQs were greater than 1.0 in the conservative scenario food chain model (see Table 8.5).

- Soil herbivorous receptors-Three metals were retained as COPCs for the meadow vole because the NOAEL EEQs were greater than 1.0 in the conservative scenario food chain model (see Table 8.5). Two metals were retained as COPCs for the bobwhite quail because the NOAEL EEQs were greater than 1.0 in the conservative scenario food chain model (see Table 8.5).

8.6 STEP 3A - REFINEMENT OF CONSERVATIVE EXPOSURE ASSUMPTIONS

Step 3a consists of a refinement of the conservative exposure assumptions/concentrations to evaluate potential risks to ecological receptors (i.e., plants, invertebrates, and wildlife receptors). The objective of the Step 3a evaluation is to further reduce the number of chemicals that are retained as COPCs to focus

any additional efforts on those chemicals causing ecological risks. Risks to terrestrial plants and invertebrates are first evaluated, followed by an evaluation of the risks to aquatic receptors. Risks to terrestrial wildlife were then evaluated by performing the food chain modeling using less conservative exposure assumptions and average chemical concentrations.

8.6.1 Risks to Terrestrial Plants and Invertebrates

The first step in the Step 3a refinement is to remove inorganic chemicals with detected concentrations similar to or below background concentrations from the list of COPCs. Although it is recognized that there are potential risks from these chemical background levels, chemicals detected at these low concentrations are not related to site activities and should not be further evaluated in the Step 3a process. Although the same can be said for organic chemicals, they are carried through the Step 3a process and discussed at the end of the risk characterization to be conservative. Tables 8.2 and 8.3 have a column that indicates if the chemical was detected at concentrations statistically greater than background concentrations. Section 5.3 of this report presents the background comparison that was conducted for the WOD.

Table 8.2 lists the COPCs that were retained for the potential to cause risks to terrestrial plants and invertebrates. The COPCs are further examined in the following sections. Note that some chemicals with concentrations below the screening values are shaded black because they are bioaccumulative and were included in the food chain model. Because these chemicals did not exceed the screening value, they are not evaluated in this section of the Step 3A refinement because risks to plants and invertebrates are not expected.

Note that there are a few small areas at the WOD site where the vegetation is either absent or stressed. A “tar-like” substance is located in this area and may be acting as a physical barrier preventing the vegetation from growing. It is also possible that chemicals under the “tar-like” substance may be toxic to plants and could be the reason for the lack of vegetation in these small areas.

Volatiles

1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, 2-butanone, 2-hexanone, acetone, carbon disulfide, isopropyl benzene, and methyl acetate were retained as COPCs because no screening values for these chemicals are available. Generally, VOCs are not considered toxic to plants and invertebrates at low concentrations. This is indicated by the relatively high BTAG screening values for other VOCs (i.e., 100 ug/kg to 300 ug/kg); maximum concentrations of 1,2,4-trimethylbenzene (5 ug/kg), 1,3,5-trimethylbenzene (4 ug/kg), 2-hexanone (20 ug/kg), carbon disulfide (13 ug/kg), and isopropylbenzene (2 ug/kg) are well

below the screening levels for other VOCs. Therefore, risks to plants and invertebrates from these VOCs are expected to be negligible because it is assumed that the toxicity of these VOCs would be similar to the toxicity for the VOCs with screening levels. These VOCs also were detected infrequently in the surface soil at WOD in 3 of 39 or 3 of 60 samples (see Table 8.2). The maximum concentration for 2-butanone (100 ug/kg), acetone (920 ug/kg), and methyl acetate (210 ug/kg) are equal to or greater than the BTAG screening levels for some of the VOCs. 2-Butanone and acetone are common laboratory contaminants and are not expected to be present in surface soil because they are very volatile. In fact, many of the acetone results were qualified because of blank contamination. Therefore, risks to plants and invertebrates from these VOCs also are expected to be negligible. Finally, methyl acetate was detected in 29 of 39 samples, but only two of those samples had concentrations that exceeded the lower screening level for the other VOCs with concentrations of 160 ug/kg (sample WOD-SS-120) and 210 ug/kg (sample WOD-SS-136). These two samples are located approximately 350 feet away from each other and lower concentrations of methyl acetate were detected in the samples located between samples WOD-SS-120 and -136. No additional toxicity data are available for methyl acetate, but given the low frequency of detection above the screening levels for other VOCs, and the spatial distribution of the two samples that exceeded the screening levels, risks to plants and invertebrates from methyl acetate are expected to be low.

PAHs

As part of this Step 3a refinement, total PAHs were evaluated in the place of individually detected PAH concentrations in the surface soil at the WOD (see Table 8.2). This was done because the toxicity of PAHs may be additive and several studies have reported toxicity data for total PAHs (Di Toro et al., 2000). Also, note that the BTAG screening level for PAHs is not based on risks to plants or invertebrates, it is based on risks to mice. The following bullets list toxicity data for plants and/or invertebrates for total PAHs:

- The Fish and Wildlife Service developed screening levels for total PAHs for plants and invertebrates of 3.1 and 20.8 mg/kg, respectively (Lingenfelser, 2000).
- After soil treatment, total PAHs in soils were reduced from 1,710 mg/kg to 98 mg/kg, and earthworm mortality decreased from 100% before treatment to 0% after treatment (USEPA, 1997b)
- After soil treatment, total PAHs in soils were reduced from 1,442 mg/kg to 36 mg/kg, and earthworm mortality decreased from 100% before treatment to 0% after treatment in a 28-day test [Environmental Canada (EC), 1994].

The Fish and Wildlife Service study had the most appropriate value. Although all three studies that evaluated risks to plants and/or invertebrates were based on mortality, the Fish and Wildlife Service values reportedly incorporated a safety factor to account for more sensitive sublethal endpoints. Therefore, the 20.8 mg/kg value developed by the Fish and Wildlife Service is appropriate as a screening value for invertebrates; the value of 3.1 mg/kg is an appropriate screening value for plants. Based on the comparison to these values, it is unlikely that earthworms or plants would be adversely affected by the levels of total PAHs in the surface soil at the WOD because the maximum concentration (2.32 mg/kg) is below the Fish and Wildlife Service values.

Benzaldehyde and Bis(2-ethylhexyl)phthalate

Benzaldehyde and bis(2-ethylhexyl)phthalate were retained as COPCs because no screening values were available for comparison.

Benzaldehyde was detected in 20 of 35 samples collected with a maximum detection of 1,500 ug/kg at location WOD-SS-135. The source of the chemical is not known but benzaldehyde is present in several plants such as hyacinth, cinnamon, sassafras, and many other species (TOXNET, 2003). Therefore, it is possible that plants are the source of the benzaldehyde at the site. Also, as discussed in Section 5.4.1, the low level and widespread occurrence of benzaldehyde does not appear to be indicative of waste activities at WOD. No toxicity data for plants or invertebrates were available for benzaldehyde, but the fact that it is found in many plants, indicates that is not likely to be toxic at the low levels in the soil.

Bis(2-ethylhexyl)phthalate was detected in 25 of 59 samples collected with a maximum detection of 2,800 ug/kg at location 3WFF16-SS9. Although a BTAG screening value is not available for bis(2-ethylhexyl)phthalate, the ORNL value for phytotoxicity is 100,000 ug/kg (Efroymson et al., 1997a). Also, an ORNL earthworm benchmark for a similar phthalate (dimethylphthalate) is 200,000 ug/kg (Efroymson et al., 1997b). The maximum concentration of bis(2-ethylhexyl) phthalate is well below these values so risks to plants and earthworms are not likely.

Aroclor-1260

Only one PCB, Aroclor-1260, was detected in surface soils at the WOD. Aroclor-1260 was detected in 2 of 60 surface soil samples and it was retained as a COPC because the maximum concentration in the surface soil exceeded the BTAG screening value. The reference for the BTAG screening level for PCBs is not presented in the source document; however, the endpoint is listed as plants. ORNL has developed a screening benchmark of 40 mg/kg for soil phytotoxicity. The ORNL benchmarks are generally considered to be very conservative values. Therefore, because the ORNL benchmark for PCBs is well

above the maximum detected Aroclor-1260 concentration (0.22 mg/kg), risks to plants are unlikely. Also, based on a review of the literature (see below), it is unlikely that the maximum detected concentration of Aroclor-1260 (0.22 mg/kg) is impacting earthworms.

- A large and significant decline in total microarthropod abundance was observed between Aroclor-1254 concentrations of 500 and 2,500 mg/kg. Therefore, toxic threshold for PCBs lies somewhere between those concentrations (Parmelee et al., 1997).

- A 14-day laboratory bioassay with crickets yielded an LC_{50} value of 1,200 mg/kg for Aroclor-1254 (Paine et al., 1993).

- Rhett et al., (1998) reported LC_{50}s of 530 mg/kg for Aroclor-1254 after 14 days and 366 mg/kg after 28 days for earthworms.

- 144 mg/kg of PCBs (primarily Aroclor-1260) was not toxic to two earthworm species after a 14-day laboratory bioassay, the EC_{50} for cocoon production was approximately 98 mg/kg, and the no observed effect concentration (NOEC) for cocoon production was approximately 72 mg/kg (Meier et al., 1997).

Although most of the studies listed above evaluated risks from Aroclor-1254, the toxicity of Aroclor-1260 to invertebrates is expected to be similar to the toxicity from Aroclor-1254. In addition, the low frequency of detection (3 percent) coupled with the low concentration indicates that PCBs are not widespread across the site and that there is not a hot spot of PCB contamination. Therefore, the concentrations of PCBs in the soil are not posing a risk to plants or invertebrates at the WOD.

Metals

Thirteen metals were retained as COPCs in surface soil because their maximum detected concentrations exceeded the screening values. None of the metals retained as COPCs were statistically determined to be above background. However, background comparisons could not be conducted for antimony or silver.

Antimony was detected in two of 40 surface soil samples and had a maximum concentration of 0.92 in sample 3WFF16-SS13. The BTAG screening value used for the COPC selection of antimony was 0.48 mg/kg, which is the level for protection of plants. Only the maximum detection exceeded the BTAG screening level. The source for the endpoint for the BTAG screening value is not listed USEPA (1995). A common conservative benchmark for evaluating risks to plants from antimony concentrations is the ORNL value for phytotoxicity of 5 mg/kg; the ORNL screening benchmarks are generally considered to be

conservative values. The maximum detection of antimony is below the ORNL screening benchmark so risks to plants are expected to be low. The antimony USEPA Ecological Soil Screening Level (SSL) for invertebrates is 78 mg/kg (USEPA, 2003a). The maximum detection of antimony in the surface soil is well below this level so risks to soil invertebrates are negligible.

Silver was detected in 28 of 51 samples and had a maximum concentration of 2.3 mg/kg at location WOD-SS-136. The BTAG screening value used for the COPC selection of silver was 0.0098 mg/kg, which is the level for protection of plants. The endpoint for the BTAG screening value is listed only as "corn" in USEPA (1995). A common conservative benchmark for evaluating risks to plants from silver concentrations is the ORNL value for phytotoxicity of 2 mg/kg; the ORNL screening benchmarks are generally considered to be conservative values. Only the maximum detection of silver exceeded the ORNL screening benchmark. In Ratte (1999), artificial soil spiked with silver showed no effects to earthworms at 62 mg/kg after 28 days, and no effects to earthworms were observed after worms were exposed to soil containing 2,000 mg/kg for 14 days. Based on data in the literature, it is unlikely that the silver in the sample with the maximum silver detection will be bioavailable. In the Silver Hazards to Fish, Wildlife, and Invertebrates: A Synoptic Review (Eisler, 1996), it is reported that silver in soils is largely immobilized by precipitation to insoluble salts and by complexation or adsorption by organic matter, clays, and manganese oxides. The total organic carbon (TOC) concentration in the sample with the maximum silver detection was very high (19.2 percent). According to Table 2.4 in the USEPA Guidance for Developing Ecological Soil Screening Levels (Eco SSLs), soil with a pH between 5.5 and 7 that contains 6 to 10 percent organic matter has a low bioavailability (USEPA, 2003). Organic matter is 1.72 times the TOC so the organic matter levels in sample WOD-SS-136 was 33 percent and the pH was 6.2, which indicates the silver in that samples will not be bioavailable. Therefore, because the detected concentration is below the ORNL plant benchmark and below the no effects levels for earthworms, and the silver is not expected to be bioavailable, risks to plants and invertebrates are expected to be negligible.

8.6.2 Risks to Aquatic Receptors

As discussed above, twelve of the surface soil samples were collected in marsh sediment so they were evaluated as both surface soils and sediment. The following discussion presents the Step 3a evaluation of these sediment marsh samples.

VOCs

2-Butanone, 2-hexanone, acetone, carbon disulfide, and methyl acetate were retained as COPCs in sediment because no screening values are available for these chemicals. As discussed above, 2-

butanone and acetone are common laboratory contaminants and are not lkely to be present in the sediment samples. 2-Hexanone and carbon disulfide, which were detected at low concentrations in 1 of 12 and 3 of 12 samples, respectively also may be due to laboratory contamination. Also, carbon disulfide is known to occur naturally and is commonly found in estuarine marshes due to microbial actions. Staubes et al. (1987) found that humus soils were stronger sources for biogenic sulfur than soils with lower organic content. Based on the high TOC in the sediment samples, it is possible that the carbon disulfide is from natural sources. The source of the methyl acetate is not known. No toxicity data are available to evaluate risks to aquatic receptors from these chemicals. However, once these chemicals migrate to a sediment location that is inundated with water, it is likely that the VOCs would mix with the surface water and volatize into the atmosphere. Therefore, risks to aquatic receptors from these chemicals are expected to be negligible.

SVOCs

As part of this Step 3A refinement, HMW PAHs, low molecular weight (LMW) PAHs, and total PAHs were evaluated in the place of individually detected PAH concentrations (see Table 8.3) in the sediment at the WOD. This was done because the toxicity of PAHs has been reported to be additive and several studies have reported toxicity data for total PAHs (Di Toro et al., 2000). Benzo(k)fluoranthene was detected in one sample at a concentration that exceeded its screening level. The screening level for total PAHs was not exceeded, however, benzo(k)fluoranthene was not included in the list of PAHs that was used for the total PAHs since it was not included in the list of PAHs used to develop the screening levels. The infrequent detection of benzo(k)fluoranthene, the high TOC level in the sediment sample in which it was detected (4.2 percent), and the fact that the total PAH concentration would be below the screening levels even if the concentration of benzo(k)fluoranthene was added to the total PAH sum, indicates that risks from PAHs to aquatic receptors are low.

Benzaldehyde was detected in 11 of the 12 marsh sediment samples collected with a maximum detection of 1,500 ug/kg at location WOD-SS-135. As discussed above, the source of the chemical is not known but benzaldehyde is present in several plants (TOXNET, 2003). The vegetation near the marsh sediment samples is very diverse. Because benzaldehyde is present in several plants, the more diverse the plant community, the more likely it is that a plant containing benzaldehyde is present. Therefore, it is possible that benzaldehyde is present from natural sources. Although no toxicity data are available to evaluate risks to aquatic receptors from benzaldehyde, the fact that it is found in many plants, indicates that it is not likely to be not toxic at the low levels it was detected in the marsh sediment.

Aroclor-1260

Aroclor-1260, the only PCB detected in the sediment samples, was retained as a COPC because the maximum concentration exceeded the BTAG screening level of 22.7 ug/kg. It was detected in two of the 12 sediment marsh samples at concentrations of 180 ug/kg (sample WOD-SS-136) and 220 ug/kg (sample WOD-SS-135). Both of the positive results were greater than or equal to the effects range-median (ER-M) for PCBs of 180 ug/kg (Long et al., 1995). The BTAG screening level, which is the effects range-low (ER-L) value from Long et al., (1995) and the ER-M are both based on sediment TOC levels of approximately one percent. The TOC values for samples WOD-SS-135 and -136 are 19.2 and 14.3 percent, respectively. Therefore, it is highly unlikely that the Aroclor-1260 will be bioavailable in those samples, at levels that will cause impacts to aquatic receptors. Also, because it was only detected in two of 59 soil sample, Aroclor-1260 does not appear to be a site-wide contaminant and may not be related to site activities.

Metals

Nine metals were retained as COPCs in the sediment at the WOD because their maximum concentrations exceeded the screening levels. Additionally, beryllium was selected as a COPC because no toxicity information was available. Of all the chemicals selected as COPCs, only silver was determined to be statistically greater than background. No statistical comparison could be done for selenium.

Silver was retained as a COPC because the maximum concentration of 2.3 mg/kg exceeded the BTAG screening level of 1.0 mg/kg. Silver was detected in eight of ten samples collected, and three of the ten samples (WOD-SS-135 through 137) had silver concentrations in excess of the BTAG sediment screening level of 1.0 mg/kg. As discussed previously, these are the three samples with the greatest TOC levels at the site ranging from 14.3 to 19.2 percent. In the Silver Hazards to Fish, Wildlife, and Invertebrates: A Synoptic Review (Eisler, 1996), it is reported that silver in soils is largely immobilized by precipitation to insoluble salts and by complexation or adsorption by organic matter, clays, and manganese oxides. Therefore, based on the high TOC and the only slight exceedances of the screening level, risks to aquatic receptors from silver in the sediment are expected to be low.

Selenium was detected in two of the twelve marsh sediment samples, with the maximum concentration of 1.5 mg/kg located at WOD-SS-135. There is no sediment BTAG screening value for selenium, but only the maximum sediment concentration exceeded the apparent effects threshold (AET) of 1.0 mg/kg as listed in Buchman (1999). As discussed previously for sample WOD-SS-136, the very high TOC level in sample WOD-SS-135 (17.5 percent) will significantly decrease the bioavailability of selenium in the

sediment marsh sample making risks to aquatic receptors unlikely at the detected concentration. Also, note that although a statistical background comparison could not be conducted for selenium, the maximum detection in the site sample was just slightly greater than the maximum concentration in the background sample (1.4 mg/kg). Therefore, the selenium likely is not related to site activities.

8.6.3 Risks to Terrestrial Wildlife

Section 8.5.3 and Table 8.5 list the chemicals that were retained as COPCs because they had NOAEL EEQs greater than 1.0 in at least one of the conservative scenario receptor models. In order to refine the list of COPCs, food chain modeling was conducted using less conservative exposure assumptions as explained in Section 8.3.

Aroclor-1260 and several metals were retained as COPCs because the NOAEL EEQs were greater than 1.0 in the conservative food chain model for at least one of the wildlife receptors. Less conservative exposure assumptions were then used to recalculate risks to wildlife as explained in Section 8.3.3. No chemicals had NOAEL or LOAEL EEQs greater than 1.0 using average input parameters and average or 95% UCL chemical concentrations so risks to wildlife from site-related chemicals are negligible.

Risks to reptiles were not quantitatively evaluated because exposure factors are not established for most species, and toxicity data are very limited. However, birds and mammals were used as a surrogate to evaluate potential risks to reptiles. As discussed above, risks to birds and/or mammals from PCBs are negligible. The exposure to site contaminants for reptiles will be lower than the exposure of birds and mammals for several reasons. Snakes and turtles consume food items other than earthworms (i.e., plants, insects, small mammals), which are likely to have lower concentrations of contaminants from the soil than earthworms. Also, as presented in USEPA (1993), the metabolic rates and food ingestion rates for reptiles are lower than those for birds and small mammals. Therefore, because the risks to birds and mammals are negligible, risks to reptiles from contaminants in the soil also are negligible based on their lower exposure to site contaminants.

8.7 ECOLOGICAL RISK UNCERTAINTY ANALYSIS

This section presents some of the uncertainties associated with ecological risk assessments.

8.7.1 Measurement and Assessment Endpoints

Measurement endpoints are used to evaluate the assessment endpoints that are selected for the ERA. For this ERA, the measures of effects are not the same as the assessment endpoints. Therefore, the

measures are used to predict effects to the assessment endpoints by selecting surrogate species that will be evaluated. For example, increased mortality of a shrew is used to assess increased mortality of the small mammal population. However, predicting mortality to a shrew may either under or overprotect the small mammal population, resulting from differences in ingestion rates, toxicity, food preferences, etc. between different species.

Several endpoints were not quantitatively evaluated in this ERA. For example, risks to reptiles and amphibians were not quantitatively evaluated because exposure factors are not established for most species, and toxicity data are very limited. Therefore, potential impacts to these species were not determined. Risks to large carnivorous and omnivorous birds and mammals were not evaluated in this ERA. Only a small portion of the food for higher trophic level species will actually come from the affected site, so it is difficult to determine the actual risks involved. By evaluating the effects to small birds and mammals, the risks to higher trophic level species is taken into account. Because risks to small mammals and birds were expected to be low or negligible, risks to higher trophic level species will be low as well.

8.7.2 Exposure Characterization

The chemical dose to terrestrial wildlife is calculated using an equation that incorporates ingestion rates, body weights, bioaccumulation factors, and other exposure factors. These exposure factors are obtained from literature studies or predicted using various equations. Ingestion rates and body weights vary between species, especially between species inhabiting different areas.

Site-specific tissue samples (i.e., plants, invertebrates) were not collected as part of this investigation. Therefore, chemical concentrations in the tissues of these receptors were estimated using various bioaccumulation factors (i.e., soil to invertebrate), in order to obtain exposure point concentrations in the food items for the food chain models. These bioaccumulation factors were derived from the literature, and most of the factors do not take into account site-specific factors such as pH, organic carbon, etc. that can affect BAFs. Therefore, there are uncertainties in the estimation of chemical concentrations in the prey items used for the food chain models.

Another uncertainty in the exposure calculation is the assumption that the chemicals in the media are 100 percent bioavailable to the receptors at the detected concentrations. This is unlikely to occur for chemicals in the environment. As is reported in Efroymson et al. (1997), "…the concentrations reported are nominal concentrations of a soluble form (i.e., a highly bioavailable form) of the chemical added to soil. Most metals in natural soils and contaminants of waste sites are in poorly available forms." Therefore, it is likely that most chemicals (especially metals) in environmental media (i.e., surface soil and sediment) are much less

bioavailable than the chemicals in the laboratory tests used to develop some of the screening levels. Bioavailability was discussed qualitatively in the ERA by evaluating the TOC data in the samples. Based on the very high TOC levels in many of the samples, especially the marsh sediment samples which had the maximum detected concentrations for several chemicals, it is likely that the bioavailability of the chemicals in those samples would be very low.

There is uncertainty in the chemical data that are collected at the site. Measured levels of chemicals are only estimates of the true site chemical concentrations. For samples that are deliberately biased toward known or suspected high concentrations, predicted doses will probably be higher than actual doses. As can be seen by the various site figures (i.e., Figure 4-3) because historic samples were only collected in the southeastern portion of the site, the dataset is being biased toward that area, even through the recent samples were collected at areas spread throughout the site. Because overall risks from the chemicals in the surface soil samples were low, and most of the metals were detected below background concentrations, the biasing of the data is not affecting the conclusions of the ERA.

As discussed earlier in this ERA, fish are exposed to chemicals in the soil/sediment at the base of the slope on an infrequent basis during flooding conditions. It was assumed that their exposure to chemicals in the soil/sediment would be lower than that of benthic invertebrates, which are in direct contact with the soil/sediment. For that reason, risks to fish and piscivorous birds were not evaluated in the ERA because other receptors that were evaluated in the ERA (i.e, invertebrates for fish and shrews for piscivorous birds) are expected to have greater risks. There are some uncertainties with not evaluating risks to fish and piscivorous birds.

Finally, because some mammals and birds have small home ranges, the food chain risks are calculated assuming that the receptors feed only at the site. This assumption over-estimates risk because it is unlikely that the receptors will obtain all their food from within the site boundaries or from the most contaminated areas of the WOD.

8.7.3 Ecological Effects Data

There is uncertainty in the ecological benchmark values. Potentially adverse impacts to terrestrial plants and invertebrates from constituents in surface soil are evaluated by comparing the COPC concentration to surface soil screening values. Few studies and little data are available for establishing soil screening values and many are based on the results of only a few studies. Also, there may be situations where the soil screening values are overpredictive of risk if sensitive species used to develop the criteria are not present. In these cases, an effort was made to identify more appropriate values in the Step 3a refinement.

The NOAELs and LOAELs selected for the surrogate wildlife species were based on species commonly used in laboratory studies (i.e., rats, mice, ducks). There is uncertainty in the application of toxicity data among species because the contaminant may be more or less toxic to the wildlife species in question then it was to the test species.

The toxicity of chemical mixtures is not well understood. The toxicity data used in the ERA to evaluate risk to ecological receptors is for individual chemicals. Chemical mixtures can affect organisms very differently than individual chemicals because of synergistic or antagonistic effects. Additionally, toxicological data were not available for some COPCs, especially the VOCs and some of the SVOCs. The lack of toxicity data for these chemicals does not impact the conclusions of the ERA, however, because VOCs are generally not considered to be toxic to ecological receptors, especially at the low concentrations in which they were detected. Also, one of the SVOCs (benzaldehyde) is present in many plants, which may be the source of the chemical at the site. This is supported by the fact that it was the most frequently detected SVOC in the soil samples, with the exception of bis(2-ethylhexyl)phthalate which is a common laboratory contaminant. Also, for the most part, its occurrence in samples does not appear to correlate with the occurrence of other chemicals. Because benzaldehyde is common in some plants, it is not likely to affect plants and invertebrates which could be exposed to benzaldehyde by ingesting plant material.

8.7.4 Risk Characterization

Risks are projected if an EEQ is greater than or equal to 1.0 regardless of the magnitude of the EEQ. Although the relationship between the magnitude of an EEQ and toxicity is not necessarily linear, the magnitude of an EEQ can be used as a rough approximation of the extent of potential risks, especially if there is sufficient confidence in the guideline used. Finally, there is uncertainty in how the predicted risks to a species at the site translate into risk to the population in the area as a whole.

During the Step 3a refinement, chemicals are evaluated in a line of evidence approach using topics discussed in Section 8.6. In cases where background comparisons could not be made and toxicological information for certain chemicals is not available, the chemicals were not kept for COC consideration. Uncertainties are inherent in this approach because quantification of the risks is not possible and some chemicals that are potentially causing toxicity are not identified.

Risks to reptiles were not quantitatively evaluated because exposure factors are not established for most species, and toxicity data are very limited. However, birds and mammals were used as a surrogate to evaluate potential risks to reptiles. Predicting risks to birds and mammals may either over- or under-predict

the risks to reptiles because of differences in ingestion rates, toxicity, food preferences, etc. Therefore, there is uncertainty involved in using risks to birds and mammals to evaluate risks to reptiles.

8.8 SUMMARY AND CONCLUSIONS

Several chemicals detected in the surface soil samples at the WOD were initially retained as COPCs because their chemical concentrations exceeded screening levels, screening levels were not available for those chemicals, or they were bioaccumulative chemicals with EEQs greater than one based on the conservative exposure scenarios. These chemicals were then re-evaluated in Step 3a of this ERA using a variety of factors such as less conservative exposure assumptions, more appropriate toxicity data based on the assessment endpoints, spatial distribution of the chemicals, and other factors to better determine risks to ecological receptors. The ecological endpoints quantitatively evaluated in this ERA were soil invertebrates, plants, aquatic receptors, and small mammals and birds that consume terrestrial plants and/or invertebrates.

In addition to the above risk-based discussions, chemical concentrations in the site samples were compared to chemical concentrations in background samples to determine if the chemical were related to site activities and if potential risks from chemical at the site are similar to background risks. Metals whose concentrations were determined to be statistically similar to background concentrations were eliminated from further discussion at the beginning of the Step 3a. Organic chemicals whose concentrations were determined to be statistically similar to background concentrations were still evaluated in Step 3a, however, to be conservative.

8.8.1 Summary of Risks to Plants and Invertebrates

Overall, risks to plants and invertebrates from chemicals detected in the surface soil are expected to be low or negligible. The chemicals were either detected at concentrations below levels where toxic responses are expected to occur, the chemicals were detected infrequently, or the spatial distribution indicated that the potentially impacted area was small.

Although as discussed above (and summarized below), the chemicals in the soil are not expected to impact plants, there are a few small areas at the WOD site where the vegetation is either absent or stressed. A “tar-like” substance is located in this area and may be acting as a physical barrier preventing the vegetation from growing. It is also possible that chemicals under the “tar-like” substance may be toxic to plants and could be the reason for the lack of vegetation in these small areas.

The following paragraphs discuss the risks for each chemical or group of chemicals that were retained as COPCs.

VOCs: Eight VOCs were retained as COPCs because screening values for these chemicals were not available. Generally, VOCs are not considered toxic to plants and invertebrates at low concentrations, which are indicated by the relatively high BTAG screening values for other VOCs. The VOCs without screening levels were generally detected at low frequencies, are common laboratory contaminants, or had few, if any, detections greater than the screening values for the other VOCs. Therefore, although toxicity information for some of the VOCs is not available, risks to plants and invertebrates from these chemicals in unlikely.

PAHs: As part of this Step 3A refinement, total PAHs were evaluated in the place of individually detected PAH concentrations in the surface soil because the toxicity of PAHs has been reported to be additive and several studies have reported toxicity data for total PAHs. The maximum total PAH concentration in the site soil samples is less than a screening level developed in one study for risk to plants and invertebrates and is below levels that caused toxicity to earthworms in two other studies. Therefore, it is unlikely that earthworms or plants would be adversely affected by the levels of total PAHs in the surface soil at the WOD because the maximum concentration is well below the values listed for toxicological effects.

Other SVOCs: Benzaldehyde and bis(2-ethylhexyl)phthalate were retained as COPCs because no screening values are available for comparison. The source of benzaldehyde is not known, but may be natural because benzaldehyde is present in several plants species (TOXNET, 2003). No toxicity data for plants or invertebrates were available for benzaldehyde, but the fact that it is found in many plants, indicates that it is not likely to be toxic at the low levels in the soil at the WOD. The maximum detection of bis(2-ethylhexyl)phthalate was below a conservative benchmark for plants, and below a conservative benchmark for earthworms for a similar phthalate. Therefore, risks to plants and invertebrates from bis(2-ethylhexyl)phthalate in the soil are not likely.

PCBs: Aroclor-1260 was the only PCB was detected in surface soil at the WOD, and it was only detected in two of 60 surface soil samples. The maximum detection was well below the conservative ORNL benchmark for plants so risks to plants are unlikely. Also, based on a review of the toxicity data for earthworms, it is unlikely that the concentrations of PCBs are impacting earthworms Finally, the low frequency of detection (3 percent) coupled with the low concentration indicates that PCB are not widespread across the site and that there is not a hot spot of PCB contamination. Therefore, the concentrations of PCBs in the soil are not posing a risk to plants or invertebrates at the WOD.

Metals: Thirteen metals were retained as COPCs in surface soils because their maximum detected concentrations exceeded the screening values. None of the metals were statistically determined to be detected at concentrations greater than background. However, background comparisons could not be conducted for antimony or silver.

Antimony: Antimony was detected in two of 40 surface soil samples. The maximum detection, however, was less than the conservative ORNL benchmark for phytotoxicity, and below the USEPA Ecological SSL for invertebrates. Therefore, risks to plants and invertebrates from antimony in the surface soil are negligible.

Silver: Silver was detected in 28 of 51 samples. Only the maximum detection was greater than the conservative ORNL benchmark for phytotoxicity, but the maximum detection was below levels in the literature that showed impacts to earthworms. The TOC concentrations in the sample with the maximum silver detection was very high (19.2 percent). Based on the high TOC and moderate soil pH levels, the bioavailability of silver in the soil is expected to be low. Therefore, risks to plants and invertebrates from site-related silver in the soil are negligible.

8.8.2 Summary of Risks to Aquatic Receptors

Twelve of the surface soil samples were marsh sediment so they were evaluated as both surface soils and sediment. The following discussion presents the Step 3a evaluation of these sediment marsh samples.

VOCs: Eight VOCs were retained as COPCs because screening values for these chemicals were not available. Generally, VOCs are not considered toxic to aquatic receptors at low concentrations. The VOCs without screening levels were generally detected at low frequencies or are common laboratory contaminants. Also, once these chemicals migrate to a sediment location that is inundated with water, it is likely that the VOCs would mix with the surface water and volatize into the atmosphere. Therefore, risks to aquatic receptors from these chemicals are expected to be negligible.

PAHs: As part of this Step 3A refinement, HMW PAHs, LMW PAHs, and total PAHs were evaluated in the place of individually detected PAH concentrations (see Table 8.3) in the sediment at the WOD because the toxicity of PAHs has been reported to be additive and several studies have reported toxicity data for total PAHs. The screening level for total PAHs was not exceeded, however, benzo(k)fluoranthene (which had one detection that exceeded the screening level) was not included in the list of PAHs that was used for the total PAHs. The infrequent detection of benzo(k)fluoranthene, the high TOC level in the sediment sample, and the fact that the total PAH concentration would still be below

the screening levels even if the concentration of benzo(k)fluoranthene was added to the total PAH sum, indicates that risks from this chemical to aquatic receptors are low.

Other SVOC: Benzaldehyde was retained as a COPC because no screening values are available for comparison. As discussed above, the source of the chemical is not known but benzaldehyde is present in several plants (TOXNET, 2003). Although no toxicity data are available to evaluated risks to aquatic receptors from benzaldehyde, the fact that is found in many plants indicates that is probably not toxic at the low levels it was detected in the marsh sediment.

PCBs: Aroclor-1260 was the only PCB was detected in marsh sediment at the WOD, and it was only detected in two of the 12 samples. Although both of the positive results were greater than or equal to the higher effects level (i.e., ER-M) for PCBs, the ER-M is based on sediment TOC levels of approximately one percent. The TOC values for two samples with PCB levels that exceeded the ER-M are 19.2 and 14.3 percent, respectively. Therefore, it is highly unlikely that the Aroclor-1260 will be bioavailable in those samples, at levels that will cause impacts to aquatic receptors.

Metals: Nine metals were retained as COPCs in surface soils because their maximum detected concentrations exceeded the screening values. Additionally, beryllium was selected as a COPC because no toxicity information was available. Of all the chemicals selected as COPCs, only silver was determined to be statistically greater than background. No statistical comparison could be done for selenium.

Silver: Silver was detected in eight of ten samples collected, and three of the ten samples had silver concentrations in excess of the BTAG sediment screening level of 1.0 mg/kg. The three samples had the greatest TOC levels at the site ranging from 14.3 to 19.2 percent. Silver in soils is largely immobilized by precipitation to insoluble salts and by complexation or adsorption by organic matter, clays, and manganese oxides. Therefore, based on the high TOC and the only slight exceedances of the screening level, risks to aquatic receptors from silver in the sediment are expected to be low.

Selenium: Selenium was detected in two of the twelve marsh sediment samples, but only the maximum sediment concentration exceeded the AET value. The very high TOC level (17.5 percent) in the sample with the maximum detection will significantly decrease the bioavailability of vanadium in the sediment marsh sample making risks to aquatic receptors unlikely at the detected concentration. Also, the maximum detection in the site sample was just slightly greater than the maximum concentration in the background sample. Therefore, the selenium likely is not related to site activities.

8.8.3 Summary of Risks to Terrestrial Wildlife

Several chemicals were retained as COPCs because they had NOAEL EEQs greater than 1.0 in the conservative food chain model for at least one of the wildlife receptors. Less conservative exposure assumptions were then used to recalculate risks to wildlife as part of the Step 3a refinement. No chemicals had NOAEL or LOAEL EEQs greater than 1.0 using average input parameters and average or 95% UCL chemical concentrations.

SOIL TYPES

AhA—Arapahoe mucky loam, 0 to 2 percent slopes, rarely flooded
AmA—Arapahoe-Melfa complex, 0 to 2 percent slopes, frequently flooded
AtD—Assateague fine sand, 2 to 35 percent slopes, rarely flooded
BeB—Beaches, 1 to 5 percent slopes
BhB—Bojac loamy sand, 2 to 6 percent slopes
BkA—Bojac sandy loam, 0 to 2 percent slopes
BoA—Bojac fine sandy loam, 0 to 2 percent slopes
CaA—Camocca fine sand, 0 to 2 percent slopes, frequently flooded
ChA—Chincoteague silt loam, 0 to 1 percent slopes, frequently flooded
DrA—Dragston fine sandy loam, 0 to 2 percent slopes
FhB—Fisherman fine sand, 0 to 6 percent slopes, occasionally flooded
FmD—Fisherman-Assateague complex, 0 to 35 percent slopes, rarely flooded
FrB—Fisherman-Camocca complex, 0 to 6 percent slopes, frequently flooded
MaA—Magotha fine sandy loam, 0 to 2 percent slopes, frequently flooded
McA—Melfa-Hobucken complex, 0 to 1 percent slopes, frequently flooded
MoB—Molena loamy sand, 0 to 6 percent slopes
MoD—Molena loamy sand, 6 to 35 percent slopes
MuA—Munden sandy loam, 0 to 2 percent slopes
NmA—Nimmo sandy loam, 0 to 2 percent slopes
PoA—Polawana mucky sandy loam, 0 to 2 percent slopes, frequently flooded
SeA—Seabrook loamy fine sand, 0 to 2 percent slopes
UpD—Udorthents and Udipsamments soils, 0 to 30 percent slopes

Ecological Risk Assessment Tiered Approach

RPM Input and Risk Management Consideration[3]

Step 8: Risk Management

Tier 1. Screening Risk Assessment (SRA): Identify pathways and compare exposure point concentrations to bench marks.

Step 1: Site visit; Pathway Identification/Problem Formulation; Toxicity Evaluation

Step 2: Exposure Estimate; Risk Calculation (SMDP)[1]

Proceed to Exit Criteria for SRA

Exit Criteria for the Screening Risk Assessment: Decision for exiting or continuing the ecological risk assessment.

1) Site passes screening risk assessment. A determination is made that the site poses acceptable risk and shall be closed out for ecological concerns.

2) Site fails screening risk assessment: The site must have both complete pathway and unacceptable risk. As a result the site will either have an interim cleanup or moves to the second tier.

Tier 2. Baseline Ecological Risk Assessment (BERA): Detailed assessment of exposure and hazard to "assessment endpoints" (ecological qualities to be protected). Develop site specific values that are protective of the environment.

Step 3a: Refinement of Conservative Exposure Assumptions[2] (SRA)----**Proceed to Exit Criteria for Step 3a**

Step 3b: Problem Formulation - Toxicity Evaluation; Assessment Endpoints; Conceptual Model; Risk Hypothesis (SMDP)

Step 4: Study Design/DQO - Line of Evidence; Measurement Endpoints; Work Plan and Sampling & Analysis Plan (SMDP)

Step 5: Verification of Field Sampling Design (SMDP)

Step 6: Site Investigation and Data Analysis (SMDP)

Step 7: Risk Characterization

Proceed to Exit Criteria for BERA

Exit Criteria Step 3a Refinement

1) If re-evaluation of the conservative exposure assumptions (SRA) support an acceptable risk determination then the site exits the ecological risk assessment process.

2) If re-evaluation of the conservative exposure assumptions (SRA) do not support an acceptable risk determination then the site continues in the Baseline Ecological Risk Assessment process. **Proceed to Step 3b.**

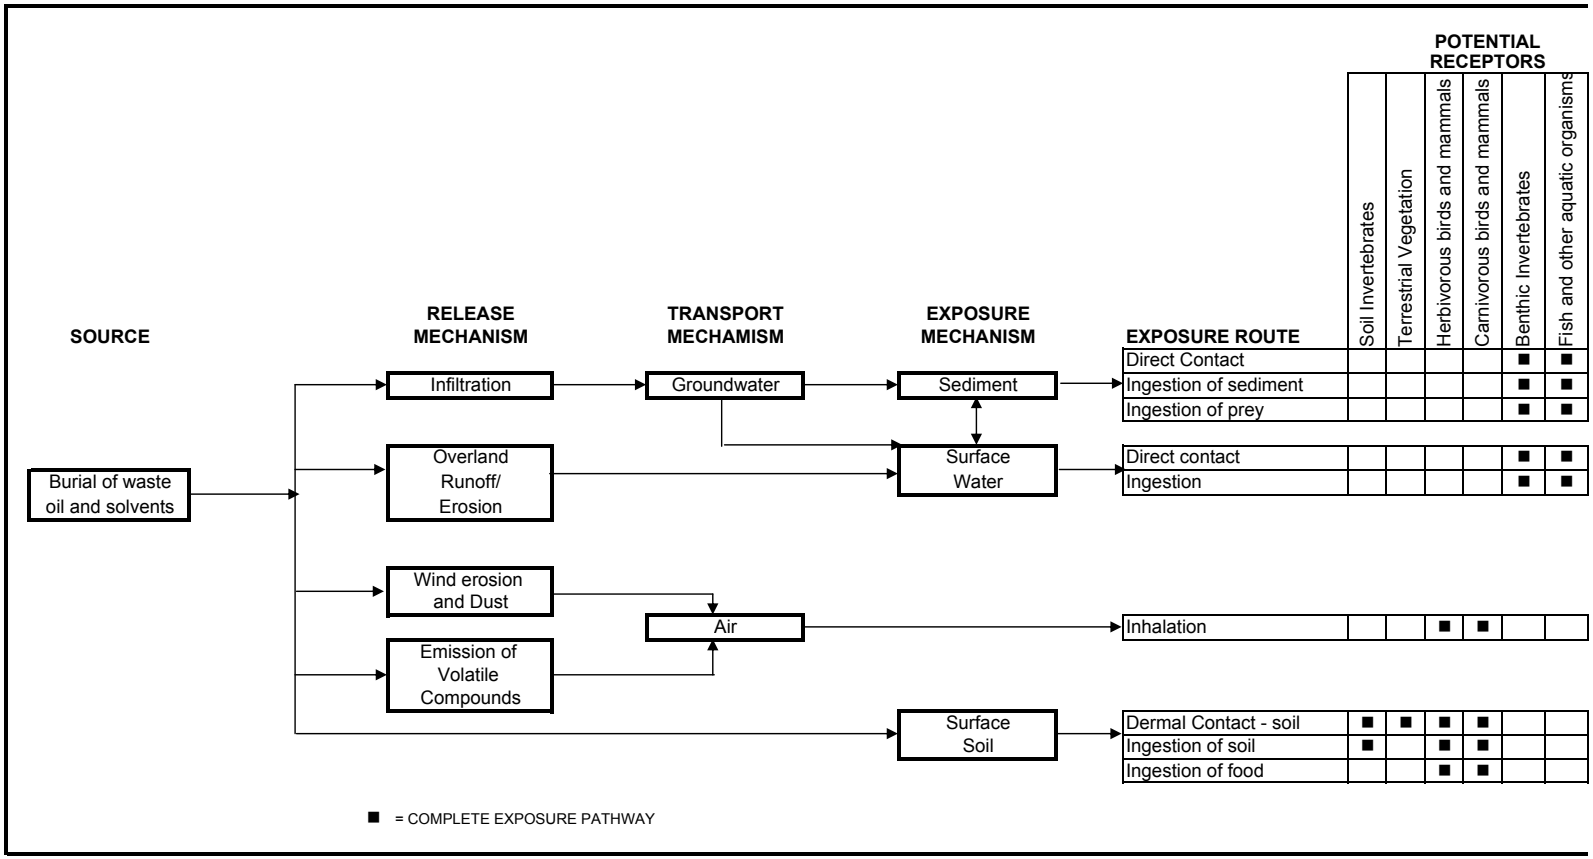
Exit Criteria Baseline Risk Assessment

1) If the site poses acceptable risk then no further evaluation and no remediation from an ecological perspective is warranted.

2) If the site poses unacceptable ecological risk and additional evaluation in the form of remedy development and evaluation is appropriate, proceed to third tier.

Tier 3. Evaluation of Remedial Alternative (RAGs C)

a. Develop site specific risk based cleanup values.



B. Qualitatively evaluate risk posed to the environment by implementation of each alternative (short term) impacts and estimate risk reduction provided by each (long-term) impacts; provide quantitative evaluation where appropriate. Weigh alternative using the remaining CERCLA 9 Evaluation Criteria. Plan for monitoring and site closeout.

Notes: 1) See EPA's 8 Steps ERA Process for requirements for each Scientific Management Decision Point (SMDP).

2) Refinement Includes but is not limited to background, bioavailability, detection frequency. Etc.

3) Risk Management is incorporated throughout the tiered approach.

Notes:

Units are ug/kg for organics, mg/kg for inorganics.
Number of sample results excludes rejected data or blank-qualified data. Duplicates are considered as one result.
Mean of all data includes positive detections and non-detected results. Detection limits are divided by two.
Number of samples may vary based on the number of usable results.

[1] Frequency of detection refers to number of times compound was detected among all samples versus total number of samples.

Notes:

Units are ug/kg for organics, mg/kg for inorganics.
Number of sample results excludes rejected data or blank-qualified data. Duplicates are considered as one result.
Mean of all data includes positive detections and non-detected results. Detection limits are divided by two.
Number of samples may vary based on the number of usable results.

[1] Frequency of detection refers to number of times compound was detected among all samples versus total number of samples.

TOC By Lloyd Kahn (mg/kg)	NA		NA		NA		NA		NA		NA		NA		NA		NA	
Data Qualifiers:																		
B -- Positive result is considered to be an artifact of blank contamination, and should not be considered present.																		
D -- Result was reported from a diluted analysis.																		
J -- Value is considered estimated due to exceedance of technical quality control criteria or because result is less than the Contract Required Quantitation Limit (CRQL).																		
K -- Positive result is considered biased high due to exceedance of technical quality control criteria.																		
L -- Positive result is considered biased low due to exceedance of technical quality control criteria.																		
R -- Positive result is considered unusable due to exceedance of technical quality control criteria.																		
U -- Value is a non-detected result as reported by the laboratory.																		
UJ -- Non-detected result is considered estimated due to exceedance of technical quality control criteria.																		
UL -- Non-detected result is considered biased low due to exceedance of technical quality control criteria.																		
UR -- Non-detected result is considered unusable due to exceedance of technical quality control criteria.																		
Y -- Laboratory qualifier not defined.																		
Z -- Laboratory qualifier denoting that positive result is presumptively present.																		
NA -- No result is available/applicable for this parameter in this sample.

Data Qualifiers:														
B -- Positive result is considered to be an artifact of blank contamination, and should not be considered present.														
J -- Value is considered estimated due to exceedance of technical quality control criteria or because result is less than the Contract Required Quantitation Limit (CRQL).														
JN														
K -- Positive result is considered biased high due to exceedance of technical quality control criteria.														
L -- Positive result is considered biased low due to exceedance of technical quality control criteria.														
R -- Positive result is considered unusable due to exceedance of technical quality control criteria.														
U -- Value is a non-detected result as reported by the laboratory.														
UJ -- Non-detected result is considered estimated due to exceedance of technical quality control criteria.														
UL -- Non-detected result is considered biased low due to exceedance of technical quality control criteria.														
UR -- Non-detected result is considered unusable due to exceedance of technical quality control criteria.														
NA -- No result is available/applicable for this parameter in this sample.

Data Qualifiers:																
B -- Positive result is considered to be an artifact of blank contamination, and should not be considered present.																
J -- Value is considered estimated due to exceedance of technical quality control criteria or because result is less than the Contract Required Quantitation Limit (CRQL).																
K -- Positive result is considered biased high due to exceedance of technical quality control criteria.																
U -- Value is a non-detected result as reported by the laboratory.																
UJ -- Non-detected result is considered estimated due to exceedance of technical quality control criteria.																
UL -- Non-detected result is considered biased low due to exceedance of technical quality control criteria.																
UR -- Non-detected result is considered unusable due to exceedance of technical quality control criteria.																
NA -- No result is available/applicable for this parameter in this sample.

Data Qualifiers:

B -- Positive result is considered to be an artifact of blank contamination, and should not be considered present.

J -- Value is considered estimated due to exceedance of technical quality control criteria or because result is less than the Contract Required Quantitation Limit (CRQL).

K -- Positive result is considered biased high due to exceedance of technical quality control criteria.

U -- Value is a non-detected result as reported by the laboratory.

UL -- Non-detected result is considered biased low due to exceedance of technical quality control criteria.

Notes: Units are mg/kg for inorganics, ug/kg for organics.
A statistical significance level (P value) of 0.05 is used for all tests that directly compare site to background. A two-sided significance level of 0.1 is used for Bartlett's test for equal variance.
UTL is the expected value for the upper 95 % quantile of the background population; there is an equal chance of the population's true 95 % quantile being either below or above this estimate.
For each test, a YES or NO decision is presented only if all assumptions are met. The overall decision (is site > background) for each chemical appears at the left and is based on four criteria:
(1) Overall decision is YES if any one of the Mann-Whitney/Gehan, Upper Ranks Test, or T-Test is YES, regardless of other test results.
(2) Overall decision is NO if at least one of Mann-Whitney/Gehan, Upper Ranks Test, or T-Test is NO, and none of the aforementioned tests are YES.
(3) Overall decision is YES/NO if Z/Fisher Test is YES/NO, respectively, and other tests are NA. Z-test is treated as lowest priority since it relies on detection frequency, not magnitude of results.
(4) Overall decision is NA if all tests are NA. (Chemicals assigned NA are still included in human health risk-based screening and/or risk assessment.)

Abbreviations:

# NDs or # Pos.	Number of non-detected (ND) or positive (Pos.) results in data set, not including rejected data or blank-qualified data.
# s or # b	Number of site (s) or background (b) samples, not including rejected data or blank-qualified data.
s = b	Standard deviation of site results must not be different from the standard deviation of background results.
P value	Probability or significance level is defined as the chance of a false positive. If P <= 0.05 then test determines site > background with 95 % confidence.
L, N, or Q	UTL is based on 95 % upper limit (using t-value) when data are lognormal (L) or normal (N). Otherwise, an upper 95 % quantile (Q) is used if there are > 18 back. points.
% ND	Mann-Whitney test used if < 40% of data Non-Detected and detect. limits uniformly below the range of positive values. If not, the Gehan Test is used.
@	Mean and standard deviations are shown of log-transformed data when distributions are of this type; ie., if an (L) code appears for the UTL test or if site and background distributions both match lognormal. (Arithmetic mean and normal standard deviation are shown only for illustration in the event that these tests are NA.)
r,k	The upper ranks test calculates the probability that k or more samples from the top r ranks of the combined site and background data set are comprised of site data if both populations are in fact equal.

TABLE 5.6
BACKGROUND COMPARISON TESTS - WASTE OIL DUMP SUBSURFACE SOIL
WOD RI REPORT
NASA WFF - WALLOPS ISLAND, VIRGINIA

Name of Test:		Detection Freq: Z or Fisher				95 % Upper Tolerance Limit (UTL)							Upper Ranks				Mann-Whitney/Gehan				Student's or Satterthwaite T-test					Bartlett's Test for Equal Standard Deviations						
Question Posed:		Site Freq. > Back.Freq.?				Site Maximum > UTL for Background Data ?							Majority are site?				Ranks of Site > Back?				Site Mean > Back. Mean ?					Site Standard Deviation =Background Std.Dev.?						
Assumptions Valid:		#ND & Pos.>=5 or use Fisher				Back. lognorm. or norm. If not, #b>18 for Quantile Test							# Site (s) in Top r				<40% ND or use Gehan				#s>2,#b>2,>=85% Pos; both norm/log					#s>2,#b>2, site & back both normal or both lognorm.						
Test Criterion:		P value <= 0.05 ?				Max >95% UTL (parametric). Or, Max >95% Quantile							P<=0.05 that #s>=k				P value <=0.05 ?				t-Value > t-Table					F-Value<=F-Table (Students T). If not, Satterthwaite

Notes: Units are mg/kg for inorganics, ug/kg for organics.
A statistical significance level (P value) of 0.05 is used for all tests that directly compare site to background. A two-sided significance level of 0.1 is used for Bartlett's test for equal variance.
UTL is the expected value for the upper 95 % quantile of the background population; there is an equal chance of the population's true 95 % quantile being either below or above this estimate.
For each test, a YES or NO decision is presented only if all assumptions are met. The overall decision (is site > background) for each chemical appears at the left and is based on four criteria:
(1) Overall decision is YES if any one of the Mann-Whitney/Gehan, Upper Ranks Test, or T-Test is YES, regardless of other test results.
(2) Overall decision is NO if at least one of Mann-Whitney/Gehan, Upper Ranks Test, or T-Test is NO, and none of the aforementioned tests are YES.
(3) Overall decision is YES/NO if Z/Fisher Test is YES/NO, respectively, and other tests are NA. Z-test is treated as lowest priority since it relies on detection frequency, not magnitude of results.
(4) Overall decision is NA if all tests are NA. (Chemicals assigned NA are still included in human health risk-based screening and/or risk assessment.)

Abbreviations:

# NDs or # Pos.	Number of non-detected (ND) or positive (Pos.) results in data set, not including rejected data or blank-qualified data.
# s or # b	Number of site (s) or background (b) samples, not including rejected data or blank-qualified data.
s = b	Standard deviation of site results must not be different from the standard deviation of background results.
P value	Probability or significance level is defined as the chance of a false positive. If P <= 0.05 then test determines site > background with 95 % confidence.
L, N, or Q	UTL is based on 95 % upper limit (using t-value) when data are lognormal (L) or normal (N). Otherwise, an upper 95 % quantile (Q) is used if there are > 18 back. points.
% ND	Mann-Whitney test used if < 40% of data Non-Detected and detect. limits uniformly below the range of positive values. If not, the Gehan Test is used.
@	Mean and standard deviations are shown of log-transformed data when distributions are of this type; ie., if an (L) code appears for the UTL test or if site and background distributions both match lognormal. (Arithmetic mean and normal standard deviation are shown only for illustration in the event that these tests are NA.)
r,k	The upper ranks test calculates the probability that k or more samples from the top r ranks of the combined site and background data set are comprised of site data if both populations are in fact equal.

Xylene (Total)	0/7					2/60	6 J	6 J	7.8	6	WOD-SS-126

Notes:

Units are in mg/kg for inorganics and ug/kg for organics.
Number of sample results excludes rejected data or blank-qualified data. Duplicates are consolidated into one result.
Mean of all data includes positive detections and non-detected results. Detection limits are divided by two.
The determination of representative concentrations is based on comparison of maximum to the 95 % UCL, which is presented in a separate table.
Frequency of detection refers to number of times compound was detected among all samples versus total number of samples.
Number of samples may vary based on the number of usable results.

chromium, hexavalent	52.00	14 - 31
cobalt	58.93	0.2 - 3,800
copper	63.54	1.4 - 333
iron	55.85	1.4 - 1,000
lead	207.19	4.5 - 7,640
magnesium	24.31	1.6 - 13.5
manganese	54.94	0.2 - 10,000
mercury	200.59	0.06 - 200
nickel	58.71	18 - 1,900
potassium	39.10	2.0 - 9.0
selenium	78.96	2.2 - 17
silver	107.87	0.13 - 110
sodium	22.99	-
thallium	204.37	45 - 96
vanadium	50.94	-
zinc	65.37	18 - 530

* = K_d values are fromTable C-4 in EPA Soil Screening Guidance: User's Guide. 9
K_d values are for pH range of 5.0 to 8.0.

TABLE 6.3
CLASSES OF SUBSTANCES EVALUATED FOR PERSISTENCE
WOD RI REPORT
NASA WFF - WALLOPS ISLAND, VIRGINIA

CLASS	SUBSTANCE	MEDIA	
		Groundwater	Soil
Metals	Antimony		X
	Arsenic	X	
	Chromium	X	
	Iron	X	
	Lead	X	
	Manganese	X	
	Silver		X
Halogenated Aliphatics	1,2-DCE(cis)	X	
	PCE	X	X
	1,2,4-Trimethylbenzene	X	X
	1,3,5-Trimethylbenzene	X	X
Monocyclic Aromatics	Benzene	X	X
	Toluene	X	X
	M, P-Xylene	X	X
	O-Xylene	X	X
	Xylene (Total)	X	X
	1,2,4-Trimethylbenzene	X	X
	1,3,5-Trimethylbenzene	X	X
Polyaromatic Hydrocarbons	Benz(a)anthracene		X
	Benzo(a)pyrene		X
	Benzo(b)fluoranthene		X
	Benzo(k)fluoranthene		X
	Chrysene		X
	Dibenzofuran		X
	Fluoranthene		X
	Pyrene		X
	2-Methylnapthalene	X	X
	Napthalene	X	X
Pesticides and PCBs	Aroclor 1260		X

TABLE 6.4

(1) Minimum/maximum detected concentration.
(2) SS/SB - Separate columns show background tests for surface/subsurface soil. Results of statistics: Y - greater than background; N - not great
NA - insufficient samples to conclude not greater than background. ND - not detected. Metals not greater than background in SS and SB were eliminated as COPCs.
(3) EPA soil to groundwater screening criteria under default parameters and DF=20 obtained from online calculator: http://risk.lsd.ornl.gov/epa/ssl
(4) Rationale Codes Selection Reason: Above Screening Levels (ASL)
Deletion Reason: No Screening Value (NSV)
Below Screening Level (BSL)
Not a Groundwater COPC (NGC)

Definitions:
N/A = Not Applicable
SQL = Sample Quantitation Limit
COPC = Chemical of Potential Concern
J = Estimated Value
K = Biased High Value
L = Biased Low Value
C = Carcinogenic
N = Non-Carcinogenic

(1) Minimum/maximum detected concentration.
(2) N/A - Refer to supporting information for background discussion.
Background statistical analysis did not include sufficient samples for adequate statistical power.
(3) Region 3 RBC for residential tap water exposure. RBCs based on noncancer (footnoted "N") were adjusted to a HQ of 1.0
(4) Rationale Codes Selection Reason: Above Screening Levels (ASL)
Deletion Reason: No Toxicity Information (NTX)
Essential Nutrient (NUT)
Below Screening Level (BSL)

Definitions: N/A = Not Applicable
SQL = Sample Quantitation Limit
COPC = Chemical of Potential Concern
L = Biased High Value
C = Carcinogenic
N = Non-Carcinogenic

TABLE 7.4 (RAGS D 3)
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY, SURFACE SOIL
WOD RI REPORT
NASA WFF - WALLOPS ISLAND, VIRGINIA

Scenario Timeframe: Current/Future
Medium: Surface Soil
Exposure Medium: Surface Soil
Exposure Point: Ingestion, Dermal Contact, or Particulate Inhalation

Chemical of Potential Concern	Units	Arithmetic Mean	95% UCL of Normal Data	Maximum Detected Concentration	Maximum Qualifier	EPC Units	Reasonable Maximum Exposure			Central Tendency		
							Medium EPC Value	Medium EPC Statistic	Medium EPC Rationale	Medium EPC Value	Medium EPC Statistic	Medium EPC Rationale
Benzo(a)pyrene	ug/kg	312	5.91E+02	1.30E+03		ug/kg	591	95%UCL-Cheby	Wt>Wno&Wlg,0.5<=lgsd	591	95%UCL-Cheby	Wt>Wno&Wlg,0.5<=lgsd

Statistics: Maximum Detected Value (Max); 95% UCL of Normal Data (95% UCL-N);
Mean of Normal Data (Mean-N); 99% UCL of Chebychev minimum variance (99% UCL-Chebmv); 95% UCL of Chebychev minimum variance (95% UCL-Chebmv);
95% UCL of H-distribution (95% UCL-H); 95% UCL of nonparametric Chebychev (95% UCL-Cheby); 97.5% UCL of nonparametric Chebychev (97.5% UCL-Cheby).
Rationale: Log Standard Deviation (lgsd); Shapiro Wilk's normal test statistic (Wno); Shapiro Wilk's table (critical) value (Wt); Shapiro Wilk's lognormal test statistic (Wlg); Number of samples in dataset (N).
Integrated Exposure Uptake Biokinetic Model (IEUBK); Arithmetic mean (AVG).
-- - Statistical UCL (t, H-, chebychev) does not apply because distributional shape uncertain for small n.

	AT-N	Averaging Time (Non-Cancer)	days	365	EPA, 1989	365	EPA, 1989	

Notes/Sources:

"Soil*" Represents surface and subsurface soils that are mixed as a result of construction activities.

^Site-specific PEF shown for WOD.

(a). Professional Judgment. 8 Hours per day of exposure based on an average workday.

(b). Professional Judgment. 26 Weeks * 6 days per week = 156 days. Off and on throughout that year

(c). Professional Judgment. 13 Weeks * 6 days per week = 78 days. Off and on throughout that year

(d). Professional Judgment. 1 Year of exposure.

EPA Group:

Acronyms: CNS = Central Nervous System; GI = Gastrointestinal Tract; and NOAEL = No Observed Adverse A - Human carcinogen

TABLE 7.32 (RAGS D 6.2)
CANCER TOXICITY DATA -- INHALATION
WOD RI REPORT
NASA WFF - WALLOPS ISLAND, VIRGINIA

Chemical of Potential Concern	Unit Risk	Units	Adjustment	Inhalation Cancer Slope Factor (1)	Units	Weight of Evidence/ Cancer Guideline Description	Source (2)	Date (MM/DD/YY)

(1) Inhalation Slope Factor (SF) - Inhalation unit risk converted to SF using the formula in HEAST, 1997.

(2) IRIS - Integrated Risk Information System (EPA, 2002)
HEAST - Health Effects Assessment Summary Tables (EPA, 1997)
EPA - NCEA - EPA National Center for Exposure Assessment

B1 - Probable human carcinogen - indicates that limited human data are available
B2 - Probable human carcinogen - indicates sufficient evidence in animals and inadequate or no evidence in humans
C - Possible human carcinogen
D - Not classifiable as a human carcinogen
E - Evidence of noncarcinogenicity

Footnotes:
(1) Frequency of detection refers to number of times compound was detected among all samples versus total number of samples. The number of sample results excludes rejected data or blank-qualified data and may va
(2) Mean of all data includes positive detections and non-detected results. Detection limits are divided by two.

Definitions:
J - Estimated value
K - Biased high value
L - Biased low value

Footnotes:

(1) See Section 5 for a discussion of background comparison.

(2) Maximum value is used if the 95% UCL is greater than the maximum.

(3) Region III BTAG Soil Screening Levels are used if available. The screening level for 1,2-dichlorobenzene was used as asuoorgate for 1,3-dichlorobenzene.

(4) EEQ is calculated by dividing the maximum concentration by the risk based screening value.

(5) The chemicals with a "BIO" rationale are included in the food chain model for terrestrial wildlife but are not COPCs for plants and invertebrates. Table 8.5 presents the chemicals that are retained as COPCs for the food chain modeling.

Definitions:

COPC = Chemical of Potential Concern
J = Estimated value
K = Biased high value
L = Biased low value
NA = Not Applicable/Not available
PCB = Polychlorinated biphenyl
UCL = Upper Confidence Limit

Rationale Codes:

For selection as a COPC

ASL = Above screening level
BIO = Bioaccumulative
NTX = No toxicity info available

For elimination as a COPC

BSL = Below screening level
NUT = Essential nutrient

TABLE 8.3

OCCURENCE, DISTRIBUTION, AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN FOR WASTE OIL DUMP - SEDIMENT
WOD RI REPORT
NASA WFF, WALLOPS ISLAND, VIRGINIA

Footnotes:

(1) See Section 5 for a discussion of background comparison.
(2) Maximum value is used if the 95% UCL is greater than the maximum.
(3) Region III BTAG Sediment Screening Levels are used if available.
(4) EEQ is calculated by dividing the maximum concentration by the risk based screening value.
(5) Bioaccumulative chemicals are not retained as COPCs in this table because food chain modeling is not being conducted for piscivorous wildlife.
(6) NOAA SQUIRT Screening Quick Reference Table - Apparent Effects Threshold
(7) Long et al., 1995
(8) NOAA SQUIRT Screening Quick Reference Table - Upper Effects Threshold

Definitions:

COPC = Chemical of Potential Concern
J = Estimated value
K = Biased high value
L = Biased low value
NA = Not Applicable/Not available
PCB = Polychlorinated biphenyl
UCL = Upper Confidence Limit

Rationale Codes:

For selection as a COPC

ASL = Above screening level
NTX = No toxicity info available

For elimination as a COPC

BSL = Below screening level
NUT = Essential nutrient

TABLE 8.4

EXPOSURE PARAMETERS FOR THE TERRESTRIAL WILDLIFE MODEL
WOD RI REPORT
NASA WFF, WALLOPS ISLAND, VIRGINIA

	Conservative Inputs		Average Inputs	
Species/Exposure Inputs	**Values**	**Units**	**Values**	**Units**
Bobwhite Quail				
Body Weight = BW	1.540E-01	kg	1.751E-01	kg
Food Ingestion Rate = If	4.880E-03	kg/day	4.080E-03	kg/day
Soil Ingestion Rate = Is	4.002E-04	kg/day	3.346E-04	kg/day
Home Range = HR	Assume 100% on site		2.860E+01	acres
Meadow Vole				
Body Weight = BW	1.700E-02	kg	3.580E-02	kg
Food Ingestion Rate = If	3.756E-03	kg/day	3.488E-03	kg/day
Soil Ingestion Rate = Is	9.014E-05	kg/day	8.371E-05	kg/day
Home Range = HR	Assume 100% on site		3.000E-02	acres
American Robin				
Body Weight = BW	7.730E-02	kg	8.040E-02	kg
Food Ingestion Rate = If	1.247E-02	kg/day	1.188E-02	kg/day
Soil Ingestion Rate = Is	3.741E-04	kg/day	1.782E-04	kg/day
Home Range = HR	Assume 100% on site		1.190E+00	acres
Short-Tailed Shrew				
Body Weight = BW	1.500E-02	kg	1.613E-02	kg
Food Ingestion Rate = If	1.600E-03	kg/day	1.430E-03	kg/day
Soil Ingestion Rate = Is	4.800E-05	kg/day	2.145E-05	kg/day
Home Range = HR	Assume 100% on site		9.699E-01	acres

Notes:

The exposure factors were derived as presented in Appendix H.2

The soil ingestion rates were calculated by multiplying the food ingestion rates by the incidental soil ingestion rates in Appendix H.2.

Notes:
- Cells are shaded if the EEQ is greater than 1.0; these chemicals are retained as COPCs for risks to terrestrial wildlife

EEQ = Ecological Effects Quotient
NOAEL = No Observed Adverse Effects Level
LOAEL = Lowest Observed Adverse Effects Level
PCB = Polychlorinated Biphenyl

TABLE 8.6

TERRESTRIAL FOOD CHAIN MODEL EEQS - 95% UCL CONCENTRATION AND AVERAGE INPUT PARAMETERS (STEP 3A)

Data Qualifiers:
B -- Positive result is considered to be an artifact of blank contamination, and should not be considered present.
J -- Value is considered estimated due to exceedance of technical quality control criteria or because result is less than the Contract Required Quantitation Limit (CRQL).
JN -- Positive result is considered presumptively present.
K -- Positive result is considered biased high due to exceedance of technical quality control criteria.
L -- Positive result is considered biased low due to exceedance of technical quality control criteria.
R -- Positive result is considered unusable due to exceedance of technical quality control criteria.
U -- Value is a non-detected result as reported by the laboratory.
UJ -- Non-detected result is considered estimated due to exceedance of technical quality control criteria.
UL -- Non-detected result is considered biased low due to exceedance of technical quality control criteria.
UR -- Non-detected result is considered unusable due to exceedance of technical quality control criteria.
NA -- No result is available/applicable for this parameter in this sample.

Data Qualifiers:
B -- Positive result is considered to be an artifact of blank contamination, and should not be considered present.
J -- Value is considered estimated due to exceedance of technical quality control criteria or because result is less than the Contract Required Quantitation Limit (CRQL).
K -- Positive result is considered biased high due to exceedance of technical quality control criteria.
U -- Value is a non-detected result as reported by the laboratory.
UJ -- Non-detected result is considered estimated due to exceedance of technical quality control criteria.
UL -- Non-detected result is considered biased low due to exceedance of technical quality control criteria.
UR -- Non-detected result is considered unusable due to exceedance of technical quality control criteria.
NA -- No result is available/applicable for this parameter in this sample.

QA/QC Checklist:

All data fields have been completed as necessary: ☐
Correct measurement units are cited in the SAMPLING DATA block: ☐
Values cited in the SAMPLING DATA block are consistent with the Groundwater Sample Log Sheet: ☐
Mulitplication is correct for each *Multiplier* table: ☐
Final calulated concentration is within the appropriate *Range Used* block: ☐
Alkalinity *Relationship* is determined appropriatly as per manufacturer (HACH) instructions: ☐
QA/QC sample (e.g., Std. Additions, etc.) frequency is appropriate as per the project planning documents: ☐
Nitrite Interference treatment was used for Nitrate test if Nitrite was detected: ☐
Title block on each page of form is initialized by person who performed this QA/QC Checklist: ☐

Sulfate (SO_4^{2-}):

Equipment: DR-850 DR-8__ Range: 0 - 70 mg/L Concentration: _____ ppm
Program/Module: _____ 91 Analysis Time: _____
Standard Solution: ☐ Results: _____ Filtered: ☐
Standard Additions: ☐ Digits Required: 0.1ml:_____ 0.2ml:_____ 0.3ml:_____
Notes:

Nitrate (NO_3^--N):

Equipment: DR-850 DR-8__ Range: 0 - 0.50 mg/L (1) Concentration: _____ ppm
Program/Module: 55 Analysis Time: _____ Filtered: ☐
Standard Solution: ☐ Results: _____ Nitrite Interference Treatment: ☐ Reagent Blank Correction: ☐
Standard Additions: ☐ Digits Required: 0.1ml:_____ 0.2ml:_____ 0.3ml:_____
Alternate forms: NO_2 _____ $NaNO_2$ _____ mg/L

Notes (1): If results are over limit use dilution method at step 3, 5ml sample 10ml DI result X3, range upto 1.5mg/L

Notes:

Nitrite (NO_2^--N):

Concentration: _____ ppm
Equipment: DR-850 DR-8__ Range: 0 - 0.350 mg/L Analysis Time: _____ Filtered: ☐
Program/Module: 62
Standard Solution: ☐ Results: _____ Reagent Blank Correction: ☐
Notes:

Manganese (Mn^{2+}):

Concentration: _____ ppm
Equipment: DR-850 DR-8__ Range: 0 - 20.0 mg/L Analysis Time: _____ Filtered: ☐
Program/Module: 525nm 41
Standard Solution: ☐ Results: _____ Digestion: ☐ Reagent Blank Correction: ☐
Standard Additions: ☐ Digits Required: 0.1ml:_____ 0.2ml:_____ 0.3ml:_____

Equipment: HACH MN-5 Range: 0 - 3 mg/L
Notes:

QA/QC Checklist:

All data fields have been completed as necessary: ☐
Correct measurement units are cited in the SAMPLING DATA block: ☐
Values cited in the SAMPLING DATA block are consistent with the Groundwater Sample Log Sheet: ☐
Mulitplication is correct for each *Multiplier* table: ☐
Final calulated concentration is within the appropriate *Range Used* block: ☐
Alkalinity *Relationship* is determined appropriatly as per manufacturer (HACH) instructions: ☐
QA/QC sample (e.g., Std. Additions, etc.) frequency is appropriate as per the project planning documents: ☐
Nitrite Interference treatment was used for Nitrate test if Nitrite was detected: ☐
Title block on each page of form is initialized by person who performed this QA/QC Checklist: ☐

QA/QC Checklist:

All data fields have been completed as necessary: ☐
Correct measurement units are cited in the SAMPLING DATA block: ☐
Values cited in the SAMPLING DATA block are consistent with the Groundwater Sample Log Sheet: ☐
Mulitplication is correct for each *Multiplier* table: ☐
Final calulated concentration is within the appropriate *Range Used* block: ☐
Alkalinity *Relationship* is determined appropriatly as per manufacturer (HACH) instructions: ☐
QA/QC sample (e.g., Std. Additions, etc.) frequency is appropriate as per the project planning documents: ☐
Nitrite Interference treatment was used for Nitrate test if Nitrite was detected: ☐
Title block on each page of form is initialized by person who performed this QA/QC Checklist: ☐

Project Site Name: NASA WFF
Project No.: CTO 848

Sample ID No.: WOD-SS-133
Sample Location: SS-133
Sampled By: VS/CM
C.O.C. No.: ___

[] Surface Soil
[] Subsurface Soil
[] Sediment
[X] Other: Marsh Sediment
[] QA Sample Type: ___

Type of Sample:
[X] Low Concentration
[] High Concentration

GRAB SAMPLE DATA:

Date: 2/19/03	Depth	Color	Description (Sand, Silt, Clay, Moisture, etc.)
Time: 1142	0-0.5'	Black to Light Brown	organic material leaf and roots to a silty sand
Method: SS Trowel			
Monitor Reading (ppm): 0.0			

COMPOSITE SAMPLE DATA:

Date:	Time	Depth	Color	Description (Sand, Silt, Clay, Moisture, etc.)
Method:				
Monitor Readings (Range in ppm):				

SAMPLE COLLECTION INFORMATION:

Analysis	Container Requirements	Collected	Other
TCL VOC	5 Gram Encore Sampler	6	
TCL SVOC, PCB	4 oz Amber Glass Wide Mouth	2	
TAL Metals, pH	4 oz Amber Glass Wide Mouth	2	
TOC, % Moisture	4 oz Amber Glass Wide Mouth	2	
Grain Size	8 oz Amber Glass Wide Mouth	2	

OBSERVATIONS / NOTES:

No PID readings were observed a slight sulfur odor was noted

Dup 04 was collected

OVERVIEW

The sample set for the Fire Training Area – NASA Wallops Island, Virginia, SDG B0187, consists of nine soil environmental samples (designated FTA-), and one trip blank (designated TB-). The trip blank was analyzed for target compound list (TCL) volatiles and all other samples were analyzed for TCL volatiles, semivolatiles, and polychlorinated biphenyls (PCBs). No field duplicate pairs were included in this SDG.

The samples were collected by Tetra Tech NUS on February 3, 2003 and analyzed by Mitkem Corporation laboratory of Warwick, Rhode Island.

All analyses were conducted using EPA SW-846 Methods 8260B for volatiles, 8270C for semivolatiles, and 8082 for PCBs.

SUMMARY

All compounds were successfully analyzed in all samples. The findings offered in this report are based upon a general review of all available data including data completeness, holding times until extraction and analysis, GC/MS instrument tuning, GC chromatographic performance tests, initial/continuing calibrations, laboratory and field quality control (QC) blank results, surrogate spike recoveries, Internal Standard (IS) areas, Matrix Spike/Matrix Spike Duplicate (MS/MSD) recoveries, Laboratory Control Spike/Laboratory Control Spike Duplicate (LCS/LCSD) recoveries, field duplicate results, compound identification, compound quantitation, and detection limits.

MINOR PROBLEMS

VOLATILE FRACTION

- The following table summarizes the compounds detected as contaminants in the laboratory blanks or field QC blanks at the maximum concentrations indicated:

Analyte	Maximum Concentration	Action Level (solid)
Acetone	14 ug/kg	140 ug/kg
Chloroform*	1 ug/L	5 ug/kg

* - Indicates compound was detected at a maximum level in a field QC blank.

Samples affected: The solid action levels apply to the soil environmental samples.

In applying the blank action levels to individual samples, adjustments were made for the sample's aliquot size, percent solids, and dilution factors. Positive results for acetone found in samples at concentrations less than the associated blank action level were qualified as false positives attributable to blank contamination, (B).

- The initial calibration relative response factors (RRFs) for acetone were less than the QC limit of 0.05. The associated non-detected results for acetone were qualified rejected (UR). Positive results are considered estimated, but data qualification was based upon more significant issues (blank qualification) as noted above.
- The initial calibration percent relative standard deviation (%RSD) for acetone exceeded the QC limit of 30%. Positive results are considered estimated, but data qualification was based upon more significant issues as noted above.
- The continuing calibration RRF for acetone was less than the QC limit of 0.05. Positive results are considered estimated, but data qualification was based upon more significant issues as noted above.
- Two surrogate recoveries exceeded the upper QC limit for sample FTA-SU-101-0708. The positive results for this sample are considered biased high (K), except where data was previously qualified estimated (J) due to concentrations below the quantitation limit.
- The internal standard area recovery for 1,4-dichlorobenzene-d4 in sample FTA-SU-101-0204 was less than the QC limit of 50%. The associated compound detection limits quantified by this internal standard were qualified estimated (UJ).
- Positive results reported at concentrations less than the quantitation limit were qualified estimated, (J).

SEMIVOLATILE FRACTION

- The continuing calibration percent difference (%D) for hexachlorocyclopentadiene exceeded the QC limit of 50%. The associated non-detected results for hexachlorocyclopentadiene were qualified estimated (UJ).
- The continuing calibration percent difference (%D) for carbazole and indeno(1,2,3-cd)pyrene exceeded the QC limit of 25%. The associated positive results for these compounds were qualified estimated (J).

NOTES

Sample FTA-SU-101-0708 was reanalyzed at a medium level dilution for 1,3,5-trimethylbenzene and 1,2,4-trimethylbenzene. The orginal concentrations for these compounds exceeded the calibration range of the instrument. The results for 1,3,5-trimethylbenzene and 1,2,4-trimethylbenzene only were reported from the diluted analysis.

Sample FTA-SS-101 was reanalyzed at a 2X dilution for fluoranthene. The original concentration for fluoranthene exceeded the calibration range of the instrument. The result for fluoranthene was reported from the diluted analysis.

Sample FTA-SU-101-0708 was reanalyzed at a 10X dilution due to matrix interference. All results were reported from the diluted analysis.

The data validator has corrected the proper field sample I.D.s which are shown on the data summary and handwritten atop the sample result sheets (Form I's). This action was necessary because the laboratory software used to generate the data report does not allow sufficient field width to list the entire field sample I.D.s from the chain of custody forms. The laboratory reported abbreviated I.D.s omitting the prefix "FTA-" and dashes.

No other problems were noted during review.

EXECUTIVE SUMMARY

Laboratory Performance: Acetone was detected in the volatile fraction laboratory blank. The RRF for acetone was less than the initial calibration and continuing calibration QC limit. Acetone exceeded the initial calibration %RSD QC limit. Three compounds exceeded continuing calibration QC limits for the semivolatile fraction.

Other Factors Affecting Data Quality: Chloroform was detected at in the trip blank. The surrogate recoveries for one sample exceeded QC limits in the volatile fraction. The internal standard recovery was less than the QC limit for one sample in the volatile fraction.

The data for these analyses were reviewed to evaluate usability with reference to the EPA "Functional Guidelines for Evaluating Organic Analyses ", as amended for use within EPA Region 3 (9/94), and the NFESC document entitled "Navy IRCDQM" (9/99).

The text of this report has been formatted to address only those problem areas affecting data quality.

"I attest that the data referenced herein were reviewed according to the agreed upon validation criteria as specified in the NFESC Guidelines and the Quality Assurance Project Plan (QAPP)."

APPENDIX A

Qualified Analytical Results

Qualifier Codes:

a	=	Lab Blank Contamination
b	=	Field Blank Contamination
c	=	Calibration (i.e., %RSDs, %Ds, ICVs, CCVs, RPDs, RRFs, etc.) Noncompliance
d	=	MS/MSD Noncompliance
e	=	LSC/LSCD Noncompliance
f	=	Laboratory Duplicate Imprecision
g	=	Field Duplicate Imprecision
h	=	Holding Time Exceedance
i	=	ICP Serial Dilution Noncompliance
j	=	GFAA PDS – GFAA MSA's r<0.995 (correlation coefficient)
k	=	ICP Interference – include ICSAB %Rs
l	=	Instrument Calibration Range Exceedance
m	=	Sample Preservation
n	=	Internal Standard Noncompliance
o	=	Poor Instrument Performance (i.e. baseline drifting)
p	=	Uncertainty Near Detection Limit (<2 x IDL for inorganics and < CRQL for organics)
q	=	Other Problems (can encompass of number of issues)
r	=	Surrogates Recovery Noncompliance
s	=	Pesticide/PCB Resolution
t	=	% Breakdown Noncompliance for DDT and Endrin
u	=	Pesticide/PCB % Difference Between Columns for Positive Results
v	=	Non-linear Calibrations, Tuning r <0.995 (correlation coefficient)

Data Qualifiers:
B -- Positive result is considered to be an artifact of blank contamination, and should not be considered present.
J -- Value is considered estimated due to exceedance of technical quality control criteria or because result is less than the Contract Required Quantitation Limit (CRQL).
K -- Positive result is considered biased high due to exceedance of technical quality control criteria.
U -- Value is a non-detected result as reported by the laboratory.
UJ -- Non-detected result is considered estimated due to exceedance of technical quality control criteria.
UR -- Non-detected result is considered unusable due to exceedance of technical quality control criteria.

WALLOPS FLIGHT FACILITY, WALLOPS ISLAND, VIRGINIA

Data Qualifiers:
J -- Value is considered estimated due to exceedance of technical quality control criteria or because result is less than the Contract Required Quantitation Limit (CRQL).
U -- Value is a non-detected result as reported by the laboratory.
UJ -- Non-detected result is considered estimated due to exceedance of technical quality control criteria.

SDG Narrative

Mitkem Corporation submits the enclosed data package in response to Tetra Tech NUS' CTO – 848, NASA Wallops Flight Facility project. Under this deliverable, analysis results are presented for one aqueous and nine soil samples that were collected on February 3, 2003, and received at Mitkem on February 4, 2003. Analyses were performed per specifications in the project's contract and the chain of custody forms. Sample identifications were shortened where necessary due to limitations in the data reporting software. A table of sample identifications showing full client ID and laboratory ID follows this narrative, along with the Mitkem Work Order.

The analyses were performed according to EPA SW-846 protocols and reported in a CLP-format for Level 4 deliverable with the exception of pH. The analysis results for pH are presented in the Mitkem format with supporting raw data.

.

The following observation and/or deviations are observed for the following analyses:

1. Overall Observation:

Where needed, manual integrations were performed to improve data quality. The corrections were reviewed and associated hardcopies generated and reported as required. Manual integrations are coded to provide the data reviewer justification for such action. The codes are labeled on the ion chromatogram signal (GC/MS signal) and chromatogram for GC based analysis as follows:

- M1 peak tailing or fronting.
- M2 peak co-elution.
- M3 rising or falling baseline.
- M4 retention time shift.
- M5 miscellaneous – under this category, the justification is explained.

The enclosed report includes the originals of all data with the exception of logbook pages and certain initial calibrations. Photocopies of logbook pages are included, with the originals maintained on file at the laboratory. The originals of initial calibrations that are shared among several cases are maintained on file at the laboratory, with photocopies included in the data package.

000001

2. Volatile Analysis:

Surrogate recovery: recoveries were within the QC limits with the exception of high recovery of 1,2-dichloroethane-d4 and bromofluorobenzene in sample SV1010708. The sample was re-analyzed at dilution with all surrogate recoveries within QC limits.

Lab control sample/lab control sample duplicate: spike recoveries and replicate RPDs were within the QC limits.

Sample analysis: sample SV1010708 initially analyzed at low level, but due to high concentration of target analytes, was re-analyzed at dilution by medium level. No other unusual observation was made for the analysis.

3. Semivolatile Analysis:

Please note that the soil samples are reported using the analyte list specified for aqueous samples. There are five compounds on the analyte list for soils not in the aqueous analyte list. These five compounds will be determined and reported through library search TIC if present in the samples.

Alkanes were determined as part of TICs. Alkanes are reported in the Alkane Narrative Report following the SDG narrative.

Surrogate recovery: recoveries were within the QC limits

Lab control sample: spike recoveries were within the QC limits.

Sample analysis: due to high concentration of 2-methylnaphthalene, sample FTASS101 was re-analyzed at 2x dilution. Sample SV1010708 was re-analyzed at 10x. Sample SV1010708 was re-analyzed at dilution even though no target analytes were determined above the instrument calibration range due to matrix interferences. No other unusual observation was made for the analysis.

4. PCBs Analysis:

Surrogate recovery: recoveries were within the QC limits with the exception of high recovery of low recovery of tetrachloro-m-xylene in both columns for samples FTASS101, SV1020204, SV1020708 and SV1030204. The samples were re-extracted with all surrogate recoveries within the QC limits.

Lab control sample/lab control sample duplicate: spike recoveries and replicate RPDs were within the QC limits.

Sample analysis: samples FTASS101, SV1020204, SV1020708 and SV1030204 were re-extracted outside of holding time. The initial analysis was within hold time, but had non-compliant surrogate recoveries. No other unusual observation was made for the analysis.

5. Metals Analysis:

Lab control sample: spike recoveries were within the QC limits.

Sample analysis: no unusual observation was made for the analysis.

6. pH Analysis:

Sample analysis: no unusual observation was made for the analysis.

7. Grain size Analysis:

Grain size analysis was performed by sub-contract laboratory RI Analytical Laboratories of Warwick, RI. The RIAL report is included following the blue section divider after the metals section of the data report.

8. TOC Analysis:

The analyses for Total Organic Carbon were subcontracted to STL Burlington of Colchester, VT. The TOC results are not available at this time, but will be submitted as a separate addendum to this report when received from STL Burlington.

The pages in this report have been numbered consecutively, starting from this narrative and ending with a page saying only "Last Page of Data Report".

I certify that this data package is in compliance, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package has been authorized by the laboratory manager or his designee, as verified by the following signature.

OVERVIEW

The sample set for the Fire Training Area – NASA Wallops Island, Virginia, SDG B0187 consists of 9 solid environmental samples (designated FTA-). All samples were analyzed for TAL metals. No field duplicate pairs were included in this SDG.

The samples were collected by Tetra Tech NUS on February 3, 2003 and analyzed by Mitkem Corporation laboratory of Warwick, Rhode Island.

All analyses were conducted using EPA SW-846 Method 6010B and 7471A.

SUMMARY

All analytes, with the exception of thallium and cadmium, were successfully analyzed in all samples. The findings offered in this report are based upon a general review of all available data including data completeness, holding times until analysis, initial/continuing calibrations, laboratory and field quality control blank results, field duplicate results, compound identification, compound quantitation, and detection limits.

MAJOR PROBLEMS

- Antimony, arsenic, cadmium, copper, nickel, and thallium were detected in ICP analysis of the Interference Check Solution (ICS) A, which is prepared from a certified source and should not contain low level analytes other than the primary mineral interferents, aluminum, calcium, iron, and magnesium. This indicates the potential for false positive spectral interferences if there are elevated sample concentrations of the primary minerals noted above. Positive results for cadmium and thallium at concentrations less than or approximately equal to the predicted interference value relative to the sample iron concentration (based on comparing the ratio of analyte concentration to iron concentration in samples versus ICS solution A) are considered false positives and were qualified rejected, (R). For antimony, cadmium, thallium, and nickel, when the observed result was greater than the expected level of interference but the concentration was not more than 10 times the expected interference, such results were qualified as biased high (K), except where superceded by the qualifier for blank contamination (B).

that depends on the sample mineral concentrations. For silver, when the detection limit was greater than the absolute value of the negative interference, but the detection limit was not more than 10 times the expected interference value affected non-detected results were qualified as biased low (UL). For positive silver and zinc results, when the sample concentration was greater than the predicted magnitude of negative interference but the concentration was not more than 10 times the expected interference, such results were qualified as biased low (L).

MINOR PROBLEMS

- The following table summarizes the analytes detected as contaminants in the soil laboratory blanks at the maximum concentrations indicated:

Analyte	Maximum Concentration	Action Level (Soil)
Antimony	4.6 ug/L	1.15 mg/kg
Copper	7.7 ug/L	1.925 mg/kg
Manganese	0.091 mg/kg	0.455 mg/kg
Potassium	653.3 ug/L	163.3 mg/kg
Sodium	795.8 ug/L	198.9 mg/kg

Samples affected: The soil action levels apply to all soil environmental samples.

In applying the blank action levels to individual samples, adjustments were made for the sample's aliquot size, percent solids, and dilution factors. Positive results for antimony, copper, potassium and sodium in soil samples at concentrations less than their associated blank action levels were qualified as false positives attributable to blank contamination, (B). No qualifications were required for manganese because all soil concentrations exceeded the associated blank action levels.

NOTES

The laboratory was contacted regarding true concentrations for ICS solution A because these values were not reported on Form 4 in the data package. The laboratory stated that no detectable metals are reportedly present in the commercially-purchased ICS solution A except the primary interferent metals.

The data validator has corrected the proper field sample I.D.s which are shown on the data summary and handwritten atop the sample result sheets (Form I's). This action was necessary because the laboratory software used to generate the data report does not allow sufficient field width to list the entire field sample I.D.s from the chain of custody forms. The laboratory reported abbreviated I.D.s omitting the prefix "FTA-" and dashes.

EXECUTIVE SUMMARY

Laboratory Performance: Several analytes were detected in ICS solution A that should not be detected and negative readings occurred for some metals. Data were qualified as rejected (R), biased high (K), or biased low (L). Several contaminants were detected in the laboratory blanks. Associated soil sample results were qualified (B) to indicate artifacts of blank contamination. ICS Form IV did not indicate whether solution A true values were non-detected versus not analyzed. The laboratory truncated sample I.D.s due to limitations in the reporting software and in one case inconsistently translated the field sample I.D.

Other Factors Affecting Data Quality: None.

The data for these analyses were reviewed to evaluate usability with reference to the EPA "Functional Guidelines for Evaluating Inorganic Analyses ", as amended for use within EPA Region 3 (4/93), and the NFESC document entitled "Navy IRCDQM" (9/99).

The text of this report has been formatted to address only those problem areas affecting data quality.

"I attest that the data referenced herein were reviewed according to the agreed upon validation criteria as specified in the NFESC Guidelines and the Quality Assurance Project Plan (QAPP)."

APPENDIX A

Qualified Analytical Results

Qualifier Codes:

a	=	Lab Blank Contamination
b	=	Field Blank Contamination
c	=	Calibration (i.e., %RSDs, %Ds, ICVs, CCVs, RPDs, RRFs, etc.) Noncompliance
d	=	MS/MSD Noncompliance
e	=	LSC/LSCD Noncompliance
f	=	Laboratory Duplicate Imprecision
g	=	Field Duplicate Imprecision
h	=	Holding Time Exceedance
i	=	ICP Serial Dilution Noncompliance
j	=	GFAA PDS – GFAA MSA's r<0.995 (correlation coefficient)
k	=	ICP Interference – include ICSAB %Rs
l	=	Instrument Calibration Range Exceedance
m	=	Sample Preservation
n	=	Internal Standard Noncompliance
o	=	Poor Instrument Performance (i.e. baseline drifting)
p	=	Uncertainty Near Detection Limit (<2 x IDL for inorganics and < CRQL for organics)
q	=	Other Problems (can encompass of number of issues)
r	=	Surrogates Recovery Noncompliance
s	=	Pesticide/PCB Resolution
t	=	% Breakdown Noncompliance for DDT and Endrin
u	=	Pesticide/PCB % Difference Between Columns for Positive Results
v	=	Non-linear Calibrations, Tuning r <0.995 (correlation coefficient)

DATA SUMMARY OF INORGANIC RESULTS
SDG B0187 - SOIL SAMPLES
WALLOPS FLIGHT FACILITY, WALLOPS ISLAND, VIRGINIA

Data Qualifiers:

B -- Positive result is considered to be an artifact of blank contamination, and should not be considered present.
K -- Positive result is considered biased high due to exceedance of technical quality control criteria.
L -- Positive result is considered biased low due to exceedance of technical quality control criteria.
R -- Positive result is considered unusable due to exceedance of technical quality control criteria.
U -- Value is a non-detected result as reported by the laboratory.
UL -- Non-detected result is considered biased low due to exceedance of technical quality control criteria.

SDG Narrative

Mitkem Corporation submits the enclosed data package in response to Tetra Tech NUS' CTO – 848, NASA Wallops Flight Facility project. Under this deliverable, analysis results are presented for one aqueous and nine soil samples that were collected on February 3, 2003, and received at Mitkem on February 4, 2003. Analyses were performed per specifications in the project's contract and the chain of custody forms. Sample identifications were shortened where necessary due to limitations in the data reporting software. A table of sample identifications showing full client ID and laboratory ID follows this narrative, along with the Mitkem Work Order.

The analyses were performed according to EPA SW-846 protocols and reported in a CLP-format for Level 4 deliverable with the exception of pH. The analysis results for pH are presented in the Mitkem format with supporting raw data.

.

The following observation and/or deviations are observed for the following analyses:

1. Overall Observation:

Where needed, manual integrations were performed to improve data quality. The corrections were reviewed and associated hardcopies generated and reported as required. Manual integrations are coded to provide the data reviewer justification for such action. The codes are labeled on the ion chromatogram signal (GC/MS signal) and chromatogram for GC based analysis as follows:

- M1 peak tailing or fronting.
- M2 peak co-elution.
- M3 rising or falling baseline.
- M4 retention time shift.
- M5 miscellaneous – under this category, the justification is explained.

The enclosed report includes the originals of all data with the exception of logbook pages and certain initial calibrations. Photocopies of logbook pages are included, with the originals maintained on file at the laboratory. The originals of initial calibrations that are shared among several cases are maintained on file at the laboratory, with photocopies included in the data package.

2. Volatile Analysis:

Surrogate recovery: recoveries were within the QC limits with the exception of high recovery of 1,2-dichloroethane-d4 and bromofluorobenzene in sample SV1010708. The sample was re-analyzed at dilution with all surrogate recoveries within QC limits.

Lab control sample/lab control sample duplicate: spike recoveries and replicate RPDs were within the QC limits.

Sample analysis: sample SV1010708 initially analyzed at low level, but due to high concentration of target analytes, was re-analyzed at dilution by medium level. No other unusual observation was made for the analysis.

3. Semivolatile Analysis:

Please note that the soil samples are reported using the analyte list specified for aqueous samples. There are five compounds on the analyte list for soils not in the aqueous analyte list. These five compounds will be determined and reported through library search TIC if present in the samples.

Alkanes were determined as part of TICs. Alkanes are reported in the Alkane Narrative Report following the SDG narrative.

Surrogate recovery: recoveries were within the QC limits

Lab control sample: spike recoveries were within the QC limits.

Sample analysis: due to high concentration of 2-methylnaphthalene, sample FTASS101 was re-analyzed at 2x dilution. Sample SV1010708 was re-analyzed at 10x. Sample SV1010708 was re-analyzed at dilution even though no target analytes were determined above the instrument calibration range due to matrix interferences. No other unusual observation was made for the analysis.

4. PCBs Analysis:

Surrogate recovery: recoveries were within the QC limits with the exception of high recovery of low recovery of tetrachloro-m-xylene in both columns for samples FTASS101, SV1020204, SV1020708 and SV1030204. The samples were re-extracted with all surrogate recoveries within the QC limits.

Lab control sample/lab control sample duplicate: spike recoveries and replicate RPDs were within the QC limits.

Sample analysis: samples FTASS101, SV1020204, SV1020708 and SV1030204 were re-extracted outside of holding time. The initial analysis was within hold time, but had non-compliant surrogate recoveries. No other unusual observation was made for the analysis.

5. Metals Analysis:

Lab control sample: spike recoveries were within the QC limits.

Sample analysis: no unusual observation was made for the analysis.

6. pH Analysis:

Sample analysis: no unusual observation was made for the analysis.

7. Grain size Analysis:

Grain size analysis was performed by sub-contract laboratory RI Analytical Laboratories of Warwick, RI. The RIAL report is included following the blue section divider after the metals section of the data report.

8. TOC Analysis:

The analyses for Total Organic Carbon were subcontracted to STL Burlington of Colchester, VT. The TOC results are not available at this time, but will be submitted as a separate addendum to this report when received from STL Burlington.

The pages in this report have been numbered consecutively, starting from this narrative and ending with a page saying only "Last Page of Data Report".

I certify that this data package is in compliance, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package has been authorized by the laboratory manager or his designee, as verified by the following signature.

SUBJECT: **WET CHEMISTRY DATA REVIEW – PH and GRAIN SIZE**
FIRE TRAINING AREA – NASA WALLOPS ISLAND, VIRGINIA
SDG B0187

SAMPLES: **3/Solid/**

FTA-SS-101
FTA-SS-102
FTA-SS-103

OVERVIEW

The sample set for the Fire Training Area – NASA Wallops Island, Virginia, SDG B0187 consists of three soil environmental samples (designated FTA-SS-). All soil samples were analyzed for pH and Grain Size. No field duplicate pairs were included in this SDG.

The samples were collected by Tetra Tech NUS on February 3, 2003 and analyzed by Mitkem Corporation laboratory of Warwick, Rhode Island.

All analyses were conducted using EPA SW-846 Method 9045C for pH and ASTM Method D422 for Grain Size.

SUMMARY

All parameters were successfully analyzed in all samples. The findings offered in this report are based upon a general review of all available data including data completeness, laboratory duplicate precision, field duplicate precision, logbook documentation, and calculations.

NOTES

The Relative Percent Difference (RPD) for the laboratory duplicate results for pH were within the quality control limit of 20%.

EXECUTIVE SUMMARY

Laboratory Performance: None.

Other Factors Affecting Data Quality: None.

The data for these analyses were reviewed to evaluate usability with reference to the EPA "Functional Guidelines for Evaluating Inorganic Analyses ", as amended for use within EPA Region 3 (4/93), and the NFESC document entitled "Navy IRCDQM" (9/99).

The text of this report has been formatted to address only those problem areas affecting data quality.

"I attest that the data referenced herein were reviewed according to the agreed upon validation criteria as specified in the NFESC Guidelines and the Quality Assurance Project Plan (QAPP)."

SDG Narrative

Mitkem Corporation submits the enclosed data package in response to Tetra Tech NUS' CTO – 848, NASA Wallops Flight Facility project. Under this deliverable, analysis results are presented for one aqueous and nine soil samples that were collected on February 3, 2003, and received at Mitkem on February 4, 2003. Analyses were performed per specifications in the project's contract and the chain of custody forms. Sample identifications were shortened where necessary due to limitations in the data reporting software. A table of sample identifications showing full client ID and laboratory ID follows this narrative, along with the Mitkem Work Order.

The analyses were performed according to EPA SW-846 protocols and reported in a CLP-format for Level 4 deliverable with the exception of pH. The analysis results for pH are presented in the Mitkem format with supporting raw data.

.

The following observation and/or deviations are observed for the following analyses:

1. Overall Observation:

Where needed, manual integrations were performed to improve data quality. The corrections were reviewed and associated hardcopies generated and reported as required. Manual integrations are coded to provide the data reviewer justification for such action. The codes are labeled on the ion chromatogram signal (GC/MS signal) and chromatogram for GC based analysis as follows:

- M1 peak tailing or fronting.
- M2 peak co-elution.
- M3 rising or falling baseline.
- M4 retention time shift.
- M5 miscellaneous – under this category, the justification is explained.

The enclosed report includes the originals of all data with the exception of logbook pages and certain initial calibrations. Photocopies of logbook pages are included, with the originals maintained on file at the laboratory. The originals of initial calibrations that are shared among several cases are maintained on file at the laboratory, with photocopies included in the data package.

2. Volatile Analysis:

Surrogate recovery: recoveries were within the QC limits with the exception of high recovery of 1,2-dichloroethane-d4 and bromofluorobenzene in sample SV1010708. The sample was re-analyzed at dilution with all surrogate recoveries within QC limits.

Lab control sample/lab control sample duplicate: spike recoveries and replicate RPDs were within the QC limits.

Sample analysis: sample SV1010708 initially analyzed at low level, but due to high concentration of target analytes, was re-analyzed at dilution by medium level. No other unusual observation was made for the analysis.

3. Semivolatile Analysis:

Please note that the soil samples are reported using the analyte list specified for aqueous samples. There are five compounds on the analyte list for soils not in the aqueous analyte list. These five compounds will be determined and reported through library search TIC if present in the samples.

Alkanes were determined as part of TICs. Alkanes are reported in the Alkane Narrative Report following the SDG narrative.

Surrogate recovery: recoveries were within the QC limits

Lab control sample: spike recoveries were within the QC limits.

Sample analysis: due to high concentration of 2-methylnaphthalene, sample FTASS101 was re-analyzed at 2x dilution. Sample SV1010708 was re-analyzed at 10x. Sample SV1010708 was re-analyzed at dilution even though no target analytes were determined above the instrument calibration range due to matrix interferences. No other unusual observation was made for the analysis.

4. PCBs Analysis:

Surrogate recovery: recoveries were within the QC limits with the exception of high recovery of low recovery of tetrachloro-m-xylene in both columns for samples FTASS101, SV1020204, SV1020708 and SV1030204. The samples were re-extracted with all surrogate recoveries within the QC limits.

Lab control sample/lab control sample duplicate: spike recoveries and replicate RPDs were within the QC limits.

Sample analysis: samples FTASS101, SV1020204, SV1020708 and SV1030204 were re-extracted outside of holding time. The initial analysis was within hold time, but had non-compliant surrogate recoveries. No other unusual observation was made for the analysis.

5. Metals Analysis:

Lab control sample: spike recoveries were within the QC limits.

Sample analysis: no unusual observation was made for the analysis.

6. pH Analysis:

Sample analysis: no unusual observation was made for the analysis.

7. Grain size Analysis:

Grain size analysis was performed by sub-contract laboratory RI Analytical Laboratories of Warwick, RI. The RIAL report is included following the blue section divider after the metals section of the data report.

8. TOC Analysis:

The analyses for Total Organic Carbon were subcontracted to STL Burlington of Colchester, VT. The TOC results are not available at this time, but will be submitted as a separate addendum to this report when received from STL Burlington.

The pages in this report have been numbered consecutively, starting from this narrative and ending with a page saying only "Last Page of Data Report".

I certify that this data package is in compliance, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package has been authorized by the laboratory manager or his designee, as verified by the following signature.

OVERVIEW

The sample set for the Fire Training Area – NASA Wallops Island, Virginia, SDG B0199, consists of twenty-six soil environmental samples (designated FTA-), one rinsate blank (designated RB-), and one trip blank (designated TB-). The trip blank was analyzed for target compound list (TCL) volatiles and all other samples were analyzed for TCL volatiles, semivolatiles, and polychlorinated biphenyls (PCBs). Two field duplicate pairs (FTA-SS-110/FTA-SS-DUP1 and FTA-SU-110-0204/FTA-SU-110-DUP2) were included in this SDG. Sample FTA-SS-DUP1, duplicate of FTA-SS-110, was analyzed for VOCs only. Sample FTA-SS-111 was analyzed for VOCs and PCBs only.

The samples were collected by Tetra Tech NUS on February 4, 2003 and analyzed by Mitkem Corporation laboratory of Warwick, Rhode Island.

All analyses were conducted using EPA SW-846 Methods 8260B for volatiles, 8270C for semivolatiles, and 8082 for PCBs.

SUMMARY

All compounds were successfully analyzed in all samples. The findings offered in this report are based upon a general review of all available data including data completeness, holding times until extraction and analysis, GC/MS instrument tuning, GC chromatographic performance tests, initial/continuing calibrations, laboratory and field quality control (QC) blank results, surrogate spike recoveries, Internal Standard (IS) areas, Matrix Spike/Matrix Spike Duplicate (MS/MSD) recoveries, Laboratory Control Spike/Laboratory

Control Spike Duplicate (LCS/LCSD) recoveries, field duplicate results, compound identification, compound quantitation, and detection limits.

MINOR PROBLEMS

VOLATILE FRACTION

- The following table summarizes the compounds detected as contaminants in the laboratory blanks or field QC blanks at the maximum concentrations indicated:

Analyte	Maximum Concentration	Action Level (solid)
Acetone	14 ug/kg	140 ug/kg
Bromoform*	2 ug/L	10 ug/kg
Chloroform*	1 ug/L	5 ug/kg
Methylene Chloride	12 ug/kg	120 ug/kg
2-Hexanone	3 ug/kg	15 ug/kg

* - Indicates compound was detected at a maximum level in a field QC blank.

Samples affected: The solid action levels apply to the soil environmental samples. It should be noted that field QC blanks do not receive qualification based on laboratory blank contamination.

In applying the blank action levels to individual samples, adjustments were made for the sample's aliquot size, percent solids, and dilution factors. Positive results for acetone, methylene chloride, and 2-hexanone in the samples at concentrations less than their associated blank action levels were qualified as false positives attributable to blank contamination, (B).

- The initial calibration percent relative standard deviation (%RSD) for acetone exceeded the QC limit of 30%. Positive results are considered estimated, but data qualification was based upon more significant issues (blank qualification) as noted above.
- Two continuing calibration percent differences (%D) for acetone exceeded the QC limit of 25%. Positive results are considered estimated, but data qualification was based upon more significant issues as noted above.
- One surrogate recovery exceeded the upper QC limit in the low level analyses for samples FTA-SU-104-0911, FTA-SU-105-0204, FTA-SU-105-0911, and FTA-SU-108-0709. The positive and non-detected results reported from these analyses were qualified estimated (J/UJ).
- The internal standard area recoveries for 1,4-dichlorobenzene-d4 in the low level analyses for samples FTA-SU-105-0204, FTA-SS-110, and FTA-SS-DUP1 were less than the lower QC limit of 50%. The detection limits for compounds associated with this internal standard were qualified estimated (UJ).
- Positive results reported at concentrations less than the quantitation limit were qualified estimated, (J).

SEMIVOLATILE FRACTION

- The continuing calibration percent difference (%D) for 4-nitroaniline exceeded the QC limit of 50%. The associated non-detected results were qualified estimated (UJ).

- The continuing calibration percent difference (%D) for carbazole, indeno(1,2,3-cd)pyrene, and benzo(g,h,i)perylene exceeded the QC limit of 25%. The associated positive results for these compounds were qualified estimated (J).
- The internal standard area recovery for perylene-d12 in sample FTA-SU-105-0204 was less than the QC limit of 50%. The associated compound positive results and detection limits quantified by this internal standard were qualified estimated (J/UJ).
- The aqueous LCS exhibited recoveries less than the lower QC limits for 2-methylphenol, 4-methylphenol, 3-nitroaniline, and 3,3'-dichlorobenzidine. The associated non-detected results were qualified biased low (UL).
- Positive results reported at concentrations less than the quantitation limit were qualified estimated, (J).

NOTES

The volatile fraction of sample FTA-SU-104-0911 was reanalyzed at a medium level dilution for 1,2,4-trimethylbenzene. The original concentration for this compound exceeded the calibration range of the instrument. Only the result for 1,2,4-trimethylbenzene was reported from the medium analysis.

The volatile fraction of sample FTA-SU-105-0204 was reanalyzed at a medium level dilution for 1,2,4-trimethylbenzene and 1,3,5-trimethylbenzene. The original concentrations for these compounds exceeded the calibration range of the instrument. Only the results for these compounds were reported from the medium analysis.

The volatile fraction of sample FTA-SU-105-0911 was reanalyzed at a medium level dilution for 1,1,1-trichloroethene, toluene, 2-hexanone, ethylbenzene, xylene (total), isopropylbenzene, 1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, and methylcyclohexane. The original concentrations for these compounds exceeded the calibration range of the instrument. Only the results for these compounds were reported from the medium analysis.

The semivolatile fraction of sample FTA-SU-105-0911 was reanalyzed at a 10X dilution due to concentrations of 2-methylnaphthalene and naphthalene over the calibration range of the instrument in the original analysis. The laboratory reported only raw data and results from the diluted analysis.

The MS/MSD recoveries for several volatile compounds exceeded or were less than the QC limits. No action is taken on MS/MSD data alone.

The LCS recoveries for vinyl chloride, bromomethane, chloroethane, and trichlorofluoromethane exceeded the QC limits. No action was taken because there were no positive detections for these compounds.

The data validator has corrected the proper field sample I.D.s which are shown on the data summary and handwritten atop the sample result sheets (Form I's). This action was necessary because the laboratory software used to generate the data report does not allow sufficient field width to list the entire field sample I.D.s from the chain of custody forms. The laboratory reported abbreviated I.D.s omitting the prefix "FTA-" and dashes.

No other problems were noted during review.

EXECUTIVE SUMMARY

Laboratory Performance: Acetone, methylene chloride, and 2-hexanone were detected in the volatile fraction laboratory blanks. The initial calibration %RSD exceeded QC limits for one compound in the volatile fraction. The continuing calibration %D exceeded QC limits for two volatile fraction compounds. The internal standard recoveries were less than the QC limit for three samples in the volatile fraction. The LCS recoveries exceeded the QC limits for four compounds in the volatile fraction. Four compounds exceeded continuing calibration QC limits for the semivolatile fraction. A semivolatile internal standard area recovery was less than the QC limit for one sample. Four recoveries were less than the QC limits for the aqueous semivolatile LCS.

Other Factors Affecting Data Quality: Bromoform was detected in the rinsate blank and chloroform was detected in the trip blank. Four samples exhibited volatile surrogate recoveries that exceeded the QC limits. Percent recoveries for several compounds exceeded or were less than the QC limits for the matrix spikes.

The data for these analyses were reviewed to evaluate usability with reference to the EPA "Functional Guidelines for Evaluating Organic Analyses ", as amended for use within EPA Region 3 (9/94), and the NFESC document entitled "Navy IRCDQM" (9/99).

The text of this report has been formatted to address only those problem areas affecting data quality.

"I attest that the data referenced herein were reviewed according to the agreed upon validation criteria as specified in the NFESC Guidelines and the Quality Assurance Project Plan (QAPP)."

DATA SUMMARY OF VOLATILE ORGANIC COMPOUND RESULTS
SDG B0199 - AQUEOUS AND SOIL SAMPLES
WALLOPS FLIGHT FACILITY, WALLOPS ISLAND, VIRGINIA

Data Qualifiers:
B -- Positive result is considered to be an artifact of blank contamination, and should not be considered present.
J -- Value is considered estimated due to exceedance of technical quality control criteria or because result is less than the Contract Required Quantitation Limit (CRQL).
U -- Value is a non-detected result as reported by the laboratory.
UJ -- Non-detected result is considered estimated due to exceedance of technical quality control criteria.
NA -- No result is available/applicable for this parameter in this sample.

DATA SUMMARY OF SEMIVOLATILE ORGANIC COMPOUND RESULTS
SDG B0199 - SOIL AND AQUEOUS SAMPLES
WALLOPS FLIGHT FACILITY, WALLOPS ISLAND, VIRGINIA

Data Qualifiers:
J -- Value is considered estimated due to exceedance of technical quality control criteria or because result is less than the Contract Required Quantitation Limit (CRQL).
U -- Value is a non-detected result as reported by the laboratory.
UJ -- Non-detected result is considered estimated due to exceedance of technical quality control criteria.
UL -- Non-detected result is considered biased low due to exceedance of technical quality control criteria.

SDG Narrative

Mitkem Corporation submits the enclosed data package in response to Tetra Tech NUS' CTO – 848, NASA Wallops Flight Facility project. Under this deliverable, analysis results are presented for two aqueous and twenty-six soil samples that were collected on February 4, 2003, and received at Mitkem on February 5, 2003. Analyses were performed per specifications in the project's contract and the chain of custody forms. Sample identifications were shortened where necessary due to limitations in the data reporting software. A table of sample identifications showing full client ID and laboratory ID follows this narrative, along with the Mitkem Work Order.

The analyses were performed according to EPA SW-846 protocols and reported in a CLP-format for Level 4 deliverable with the exception of pH. The analysis results for pH are presented in the Mitkem format with supporting raw data.

.

The following observation and/or deviations are observed for the following analyses:

1. Overall Observation:

Where needed, manual integrations were performed to improve data quality. The corrections were reviewed and associated hardcopies generated and reported as required. Manual integrations are coded to provide the data reviewer justification for such action. The codes are labeled on the ion chromatogram signal (GC/MS signal) and chromatogram for GC based analysis as follows:

- M1 peak tailing or fronting.
- M2 peak co-elution.
- M3 rising or falling baseline.
- M4 retention time shift.
- M5 miscellaneous – under this category, the justification is explained.

The enclosed report includes the originals of all data with the exception of logbook pages and certain initial calibrations. Photocopies of logbook pages are included, with the originals maintained on file at the laboratory. The originals of initial calibrations that are shared among several cases are maintained on file at the laboratory, with photocopies included in the data package.

2. Volatile Analysis:

Surrogate recovery: recoveries were within the QC limits with the exception of high recovery of 1,2-dichloroethane-d4 in samples FTASS111MS and SV1080709 and high recovery of bromofluorobenzene in samples SV1040911, SV1050204 and SV1050911. Sample SV1080911 was re-analyzed with 1,2-dichloroethane-d4 with QC limits and low recovery of bromofluorobenzene. Samples SV1040911, SV1050204 and SV1050911 were re-analyzed at dilution with all surrogate recoveries within QC limits.

Lab control sample/lab control sample duplicate: spike recoveries were within the QC limits with the exception of high recovery of bromomethane inV6XLCS and high recovery of vinyl chloride, bromomethane, chloroethane and trichlorofluoromethane in V6ELCS. Replicate RPDs were within the QC limits.

Matrix spike/matrix spike duplicate: duplicate matrix spikes were performed on samples FTASS111 and SV1110204. Spike recoveries were within the QC limits with the exception of several compounds in both the matrix spike and matrix spike duplicate for sample FTASS111 and SV1110204. Replicate RPDs were within the QC limits with the exception of methylene chloride for sample FTASS111.

Sample analysis: samples SV1040911, SV1050204 and SV1050911 were initially analyzed at low level, but due to high concentration of target analytes, were re-analyzed at dilution by medium level. Internal standard area counts were within the QC criteria with the exception of sample SV1050204, FTASS110, FTASSDUP1 and SV1080709RE. Sample SV1050204 was re-analyzed at dilution with all internal standard area counts within QC criteria. No other unusual observation was made for the analysis.

3. Semivolatile Analysis:

Please note that the soil samples are reported using the analyte list specified for aqueous samples. There are five compounds on the analyte list for soils not in the aqueous analyte list. These five compounds will be determined and reported through library search TIC if present in the samples.

Alkanes were determined as part of TICs. Alkanes are reported in the Alkane Narrative Report following the SDG narrative.

Surrogate recovery: recoveries were within the QC limits

Lab control sample: spike recoveries were within the QC limits with the exception of low recovery of 2-methylphenol, 4-methylphenol, 3-nitroaniline and 3,3'-dichlorobenzidine in S1CLCS.

Matrix spike/matrix spike duplicate: duplicate matrix spikes were performed on sample SV1110204. Spike recoveries and replicate RPDs were within the QC limits.

Sample analysis: due to high concentration of target analytes, sample SV1050911 was re-analyzed at 10x dilution. No other unusual observation was made for the analysis.

4. PCBs Analysis:

Surrogate recovery: recoveries were within the QC limits.

Lab control sample/lab control sample duplicate: spike recoveries and replicate RPDs were within the QC limits.

Matrix spike/matrix spike duplicate: duplicate matrix spikes were performed on sample SV1110204. Spike recoveries and replicate RPDs were within the QC limits.

Sample analysis: the method blank and lab control sample for the associated aqueous sample has a low reporting limit. These samples were extracted with samples requiring a lower reporting limit. No other unusual observation was made for the analysis.

5. Metals Analysis (SDG A):

Due to the large number of samples, metals results are arranged into two Sample Delivery Groups, SDG B0199A and B0199B. Each SDG includes a matrix spike/duplicate analysis. Results are qualified where necessary for those samples associated with each spike/duplicate. Raw analysis data for both SDGs follow Form 14 for SDG B0220B.

Lab control sample: spike recoveries were within the QC limits.

Matrix spike: matrix spike was performed on sample FTASS111. Spike recoveries were within the QC limits with the exception of antimony. Antimony is flagged with an "N" flag on Form 1's. A post digest spike was performed for antimonywith spike recovery within QC limits.\.

Matrix duplicate: matrix duplicate was performed on sample FTASS111. Replicate RPDs were within the QC limits.

Sample analysis: no other unusual observation was made for the analysis.

6. Metals Analysis (SDG B):

Lab control sample: spike recoveries were within the QC limits.

Matrix spike: matrix spike was performed on samples SV1110204 and RB020403. Spike recoveries were within the QC limits. The mercury spike and %Recovery are incorrect on Form 5's due to the software. The mercury spike added and %Recovery were manually corrected.

Matrix duplicate: matrix duplicate was performed on samples SV1110204 and RB020403. Replicate RPDs were within the QC limits.

Sample analysis: no other unusual observation was made for the analysis.

7. pH Analysis:

Sample analysis: no unusual observation was made for the analysis.

8. Grain size Analysis:

Grain size analysis was performed by sub-contract laboratory RI Analytical Laboratories of Warwick, RI. The RIAL report is included following the blue section divider after the metals section of the data report.

9. TOC Analysis:

The analyses for Total Organic Carbon were subcontracted to STL Burlington of Colchester, VT. The TOC results are not available at this time, but will be submitted as a separate addendum to this report when received from STL Burlington.

The pages in this report have been numbered consecutively, starting from this narrative and ending with a page saying only "Last Page of Data Report".

I certify that this data package is in compliance, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package has been authorized by the laboratory manager or his designee, as verified by the following signature.

OVERVIEW

The sample set for the Fire Training Area – NASA Wallops Island, Virginia, SDG B0199 consists of 26 solid environmental samples (designated FTA-) and one rinsate blank (designated RB-). All samples were analyzed for TAL metals. Two field duplicate pairs (FTA-SS-110/FTA-SS-DUP1 and FTA-SU-110-0204/FTA-SU-110-DUP2) were included in this SDG.

The samples were collected by Tetra Tech NUS on February 3, 2003 and analyzed by Mitkem Corporation laboratory of Warwick, Rhode Island.

All analyses were conducted using EPA SW-846 Method 6010B, 7470A, and 7471A.

SUMMARY

All analytes, with the exception of thallium and cadmium, were successfully analyzed in all samples. The findings offered in this report are based upon a general review of all available data including data completeness, holding times until analysis, initial/continuing calibrations, laboratory and field quality control blank results, field duplicate results, compound identification, compound quantitation, and detection limits.

MAJOR PROBLEMS

SDG B0199A

- Arsenic, cadmium, copper, lead, manganese, nickel, and thallium were detected in ICP analysis of the Interference Check Solution (ICS) A, which is prepared from a certified source and should not contain low level analytes other than the primary mineral interferents, aluminum, calcium, iron, and magnesium. This indicates the potential for false positive spectral interferences if there are elevated sample concentrations of the primary minerals noted above. Positive results for cadmium and thallium at concentrations less than or approximately equal to the predicted interference value relative to the sample iron concentration (based on comparing the ratio of analyte concentration to iron concentration in samples versus ICS solution A) are considered false positives and were qualified rejected, (R). For arsenic, cadmium, copper, nickel, and thallium, when the observed result was greater than the expected level of interference but the concentration was not more than 10 times the expected interference, such results were qualified as biased high (K). For copper, several results were qualified for another issue that supercedes (blank contamination) ICP interference.
- Antimony, barium, selenium, silver, and vanadium exhibited negative concentrations with absolute values greater than the IDL in ICS solution A, which indicates the potential for negative bias to an extent that depends on the sample mineral concentrations. For antimony and silver, when the detection limit was greater than the absolute value of the negative interference, and the detection limit was more than 10 times the expected interference value affected non-detected results were qualified as rejected (UR). For antimony and selenium, when the detection limit was greater than the absolute value of the negative interference, but the detection limit was not more than 10 times the expected interference value affected non-detected results were qualified as biased low (UL). For positive antimony results, when the sample concentration was greater than the predicted magnitude of negative interference but the concentration was not more than 10 times the expected interference, such results were qualified as biased low (L).

SDG B0199B

- Arsenic, cadmium, copper, lead, manganese, nickel, and thallium were detected in ICP analysis of the Interference Check Solution (ICS) A, which is prepared from a certified source and should not contain low level analytes other than the primary mineral interferents, aluminum, calcium, iron, and magnesium. This indicates the potential for false positive spectral interferences if there are elevated sample concentrations of the primary minerals noted above. Positive results for thallium at concentrations less than or approximately equal to the predicted interference value relative to the sample iron concentration (based on comparing the ratio of analyte concentration to iron concentration in samples versus ICS solution A) are considered false positives and were qualified rejected, (R). For arsenic, copper, and nickel, when the observed result was greater than the expected level of interference but the concentration was not more than 10 times the expected interference, such results were qualified as biased high (K). For copper, several results were qualified for another issue that supercedes (blank contamination) ICP interference.
- Antimony, barium, cobalt, selenium, silver, and vanadium exhibited negative concentrations with absolute values greater than the IDL in ICS solution A, which indicates the potential for negative bias to an extent that depends on the sample mineral concentrations. For antimony and silver, when the detection limit was greater than the absolute value of the negative interference, and the detection limit was more than 10 times the expected interference value affected non-detected results were qualified as rejected (UR). For antimony and selenium, when the detection limit was greater than the absolute value of the negative interference, but the detection limit was not more than 10 times the expected interference value affected non-detected results were qualified as biased low (UL).

MINOR PROBLEMS

- The following table summarizes the analytes detected as contaminants in the soil laboratory blanks at the maximum concentrations indicated:

Analyte	Maximum Concentration	Action Level (Soil)
Barium	0.25 mg/kg	1.25 mg/kg
Copper	8.5 ug/L	2.125 mg/kg
Manganese	0.911 mg/kg	4.55 mg/kg
Potassium	194 mg/kg	970 mg/kg
Sodium	208 mg/kg	1040 mg/kg

Samples affected: The soil action levels apply to all soil environmental samples.

In applying the blank action levels to individual samples, adjustments were made for the sample's aliquot size, percent solids, and dilution factors. Positive results for copper, potassium and sodium in soil samples at concentrations less than their associated blank action levels were qualified as false positives attributable to blank contamination, (B). No qualifications were required for barium or manganese because all soil concentrations exceeded the associated blank action levels.

- The laboratory duplicate relative percent difference (RPD) for manganese exceeded the QC limit of 35% for SDG B0199B. The associated soil results for manganese were qualified as estimated (J).
- The percent recovery (%R) for antimony was less than the lower QC limit of 75% for both SDGs B0199A and B0199B. The associated soil results and detection limits were qualified as biased low (L/UL), except where superceded by rejection (R) for ICP interference.
- The field duplicate RPD for manganese exceeded the QC limit of 50% for field duplicate pair FTA-SS-110 and FTA-SS-DUP1. The results for manganese for this field duplicate pair were qualified as estimated (J).
- Field duplicate RPDs for aluminum, barium, beryllium, chromium, magnesium, vanadium, and zinc exceeded the QC limit of 50% for field duplicate pair FTA-SU-110-0204 and FTA-SU-DUP2. The results for these analytes for this field duplicate pair were qualified as estimated (J).

NOTES

The laboratory was contacted regarding true concentrations for ICS solution A because these values were not reported on Form 4 in the data package. The laboratory stated that no detectable metals are reportedly present in the commercially-purchased ICS solution A except the primary interferent metals.

The data validator has corrected the proper field sample I.D.s which are shown on the data summary and handwritten atop the sample result sheets (Form I's). This action was necessary because the laboratory software used to generate the data report does not allow sufficient field width to list the entire field sample I.D.s from the chain of custody forms. The laboratory reported abbreviated I.D.s omitting the prefix "FTA-" and dashes.

EXECUTIVE SUMMARY

Laboratory Performance: Several analytes were detected in ICS solution A that should not be detected and negative readings occurred for some metals. Data were qualified as rejected (R), biased high (K), or biased low (L/UL). Several contaminants were detected in the laboratory blanks. Associated soil sample results were qualified (B) to indicate artifacts of blank contamination. The laboratory duplicate RPD exceeded QC criteria for one analyte. ICS Form IV did not indicate whether solution A true values were non-detected versus not analyzed. The laboratory truncated sample I.D.s due to limitations in the reporting software and in one case inconsistently translated the field sample I.D.

Other Factors Affecting Data Quality: Antimony recoveries were less than the lower QC limit in two matrix spike samples. Several analytes exceeded QC criteria for field duplicate precision for the field duplicate pairs.

The data for these analyses were reviewed to evaluate usability with reference to the EPA "Functional Guidelines for Evaluating Inorganic Analyses ", as amended for use within EPA Region 3 (4/93), and the NFESC document entitled "Navy IRCDQM" (9/99).

The text of this report has been formatted to address only those problem areas affecting data quality.

"I attest that the data referenced herein were reviewed according to the agreed upon validation criteria as specified in the NFESC Guidelines and the Quality Assurance Project Plan (QAPP)."

DATA SUMMARY OF INORGANIC RESULTS
SDG B0199 - AQUEOUS AND SOIL SAMPLES
WALLOPS FLIGHT FACILITY, WALLOPS ISLAND, VIRGINIA

Data Qualifiers:
B -- Positive result is considered to be an artifact of blank contamination, and should not be considered present.
J -- Value is considered estimated due to exceedance of technical quality control criteria or because result is less than the Contract Required Quantitation Limit (CRQL).
K -- Positive result is considered biased high due to exceedance of technical quality control criteria.
L -- Positive result is considered biased low due to exceedance of technical quality control criteria.
R -- Positive result is considered unusable due to exceedance of technical quality control criteria.
U -- Value is a non-detected result as reported by the laboratory.
UL -- Non-detected result is considered biased low due to exceedance of technical quality control criteria.
UR -- Non-detected result is considered unusable due to exceedance of technical quality control criteria.

Database source file: S:\RITCHIEM\WALLOPS ISLAND\FTA\B0199\M_B0199_A.DBF data retrieved on: 04/29/03

Qualifier Codes:

a	=	Lab Blank Contamination
b	=	Field Blank Contamination
c	=	Calibration (i.e., %RSDs, %Ds, ICVs, CCVs, RPDs, RRFs, etc.) Noncompliance
d	=	MS/MSD Noncompliance
e	=	LSC/LSCD Noncompliance
f	=	Laboratory Duplicate Imprecision
g	=	Field Duplicate Imprecision
h	=	Holding Time Exceedance
i	=	ICP Serial Dilution Noncompliance
j	=	GFAA PDS – GFAA MSA's r<0.995 (correlation coefficient)
k	=	ICP Interference – include ICSAB %Rs
l	=	Instrument Calibration Range Exceedance
m	=	Sample Preservation
n	=	Internal Standard Noncompliance
o	=	Poor Instrument Performance (i.e. baseline drifting)
p	=	Uncertainty Near Detection Limit (<2 x IDL for inorganics and < CRQL for organics)
q	=	Other Problems (can encompass of number of issues)
r	=	Surrogates Recovery Noncompliance
s	=	Pesticide/PCB Resolution
t	=	% Breakdown Noncompliance for DDT and Endrin
u	=	Pesticide/PCB % Difference Between Columns for Positive Results
v	=	Non-linear Calibrations, Tuning r <0.995 (correlation coefficient)

SDG Narrative

Mitkem Corporation submits the enclosed data package in response to Tetra Tech NUS' CTO – 848, NASA Wallops Flight Facility project. Under this deliverable, analysis results are presented for two aqueous and twenty-six soil samples that were collected on February 4, 2003, and received at Mitkem on February 5, 2003. Analyses were performed per specifications in the project's contract and the chain of custody forms. Sample identifications were shortened where necessary due to limitations in the data reporting software. A table of sample identifications showing full client ID and laboratory ID follows this narrative, along with the Mitkem Work Order.

The analyses were performed according to EPA SW-846 protocols and reported in a CLP-format for Level 4 deliverable with the exception of pH. The analysis results for pH are presented in the Mitkem format with supporting raw data.

The following observation and/or deviations are observed for the following analyses:

1. Overall Observation:

Where needed, manual integrations were performed to improve data quality. The corrections were reviewed and associated hardcopies generated and reported as required. Manual integrations are coded to provide the data reviewer justification for such action. The codes are labeled on the ion chromatogram signal (GC/MS signal) and chromatogram for GC based analysis as follows:

- M1 peak tailing or fronting.
- M2 peak co-elution.
- M3 rising or falling baseline.
- M4 retention time shift.
- M5 miscellaneous – under this category, the justification is explained.

The enclosed report includes the originals of all data with the exception of logbook pages and certain initial calibrations. Photocopies of logbook pages are included, with the originals maintained on file at the laboratory. The originals of initial calibrations that are shared among several cases are maintained on file at the laboratory, with photocopies included in the data package.

2. Volatile Analysis:

Surrogate recovery: recoveries were within the QC limits with the exception of high recovery of 1,2-dichloroethane-d4 in samples FTASS111MS and SV1080709 and high recovery of bromofluorobenzene in samples SV1040911, SV1050204 and SV1050911. Sample SV1080911 was re-analyzed with 1,2-dichloroethane-d4 with QC limits and low recovery of bromofluorobenzene. Samples SV1040911, SV1050204 and SV1050911 were re-analyzed at dilution with all surrogate recoveries within QC limits.

Lab control sample/lab control sample duplicate: spike recoveries were within the QC limits with the exception of high recovery of bromomethane inV6XLCS and high recovery of vinyl chloride, bromomethane, chloroethane and trichlorofluoromethane in V6ELCS. Replicate RPDs were within the QC limits.

Matrix spike/matrix spike duplicate: duplicate matrix spikes were performed on samples FTASS111 and SV1110204. Spike recoveries were within the QC limits with the exception of several compounds in both the matrix spike and matrix spike duplicate for sample FTASS111 and SV1110204. Replicate RPDs were within the QC limits with the exception of methylene chloride for sample FTASS111.

Sample analysis: samples SV1040911, SV1050204 and SV1050911 were initially analyzed at low level, but due to high concentration of target analytes, were re-analyzed at dilution by medium level. Internal standard area counts were within the QC criteria with the exception of sample SV1050204, FTASS110, FTASSDUP1 and SV1080709RE. Sample SV1050204 was re-analyzed at dilution with all internal standard area counts within QC criteria. No other unusual observation was made for the analysis.

3. Semivolatile Analysis:

Please note that the soil samples are reported using the analyte list specified for aqueous samples. There are five compounds on the analyte list for soils not in the aqueous analyte list. These five compounds will be determined and reported through library search TIC if present in the samples.

Alkanes were determined as part of TICs. Alkanes are reported in the Alkane Narrative Report following the SDG narrative.

Surrogate recovery: recoveries were within the QC limits

Lab control sample: spike recoveries were within the QC limits with the exception of low recovery of 2-methylphenol, 4-methylphenol, 3-nitroaniline and 3,3'-dichlorobenzidine in S1CLCS.

Matrix spike/matrix spike duplicate: duplicate matrix spikes were performed on sample SV1110204. Spike recoveries and replicate RPDs were within the QC limits.

Sample analysis: due to high concentration of target analytes, sample SV1050911 was re-analyzed at 10x dilution. No other unusual observation was made for the analysis.

4. PCBs Analysis:

Surrogate recovery: recoveries were within the QC limits.

Lab control sample/lab control sample duplicate: spike recoveries and replicate RPDs were within the QC limits.

Matrix spike/matrix spike duplicate: duplicate matrix spikes were performed on sample SV1110204. Spike recoveries and replicate RPDs were within the QC limits.

Sample analysis: the method blank and lab control sample for the associated aqueous sample has a low reporting limit. These samples were extracted with samples requiring a lower reporting limit. No other unusual observation was made for the analysis.

5. Metals Analysis (SDG A):

Due to the large number of samples, metals results are arranged into two Sample Delivery Groups, SDG B0199A and B0199B. Each SDG includes a matrix spike/duplicate analysis. Results are qualified where necessary for those samples associated with each spike/duplicate. Raw analysis data for both SDGs follow Form 14 for SDG B0220B.

Lab control sample: spike recoveries were within the QC limits.

Matrix spike: matrix spike was performed on sample FTASS111. Spike recoveries were within the QC limits with the exception of antimony. Antimony is flagged with an "N" flag on Form 1's. A post digest spike was performed for antimonywith spike recovery within QC limits.\.

Matrix duplicate: matrix duplicate was performed on sample FTASS111. Replicate RPDs were within the QC limits.

Sample analysis: no other unusual observation was made for the analysis.

6. Metals Analysis (SDG B):

Lab control sample: spike recoveries were within the QC limits.

Matrix spike: matrix spike was performed on samples SV1110204 and RB020403. Spike recoveries were within the QC limits. The mercury spike and %Recovery are incorrect on Form 5's due to the software. The mercury spike added and %Recovery were manually corrected.

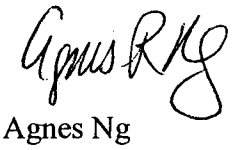
Matrix duplicate: matrix duplicate was performed on samples SV1110204 and RB020403. Replicate RPDs were within the QC limits.

Sample analysis: no other unusual observation was made for the analysis.

7. pH Analysis:

Sample analysis: no unusual observation was made for the analysis.

8. Grain size Analysis:



Grain size analysis was performed by sub-contract laboratory RI Analytical Laboratories of Warwick, RI. The RIAL report is included following the blue section divider after the metals section of the data report.

9. TOC Analysis:

The analyses for Total Organic Carbon were subcontracted to STL Burlington of Colchester, VT. The TOC results are not available at this time, but will be submitted as a separate addendum to this report when received from STL Burlington.

The pages in this report have been numbered consecutively, starting from this narrative and ending with a page saying only "Last Page of Data Report".

I certify that this data package is in compliance, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package has been authorized by the laboratory manager or his designee, as verified by the following signature.

NOTES

1 - When both results are > or = 5xCRQL/MDL, the acceptance limit is the relative percent difference must be < or = 30% for aqueous and air samples and must be < 50% for solid samples.
2 - When at least one of the results is < 5x CRQL/MDL, the acceptance limit is the difference between the results must be < or = 2xCRQL/MDL for aqueous and air samples and < or = 4xCRQL/MDL for solid samples.
Q - The qualifier is entered to indicate if the anlayte was not detected or qualitatively questionable in the sample.
U - the compound was not detected in the sample at or above the associated numerical value.
NC - The RPD was not calculated because one of the results was not detected; the acceptance limit used is the difference between the results must be < or = 2xCRQL/MDL for aqueous and air samples and < or = 4xCRQL/MDL for solid samples.
J - The positive results should be considered estimated.
B - The result should be considered non-detected or qualitatively questionable due to blank contamination.
IN - The results are acceptable.

COMMENTS

SUBJECT: WET CHEMISTRY DATA REVIEW – PH and GRAIN SIZE
FIRE TRAINING AREA – NASA WALLOPS ISLAND, VIRGINIA
SDG B0199

SAMPLES: 9/Solid/

FTA-SS-104	FTA-SS-107	FTA-SS-110
FTA-SS-105	FTA-SS-108	FTA-SS-DUP1
FTA-SS-106	FTA-SS-109	FTA-SS-111

OVERVIEW

The sample set for the Fire Training Area – NASA Wallops Island, Virginia, SDG B0199 consists of nine soil environmental samples (designated FTA-SS-). All soil samples were analyzed for pH and Grain Size. One field duplicate pair (FTA-SS-110/FTA-SS-DUP1) was included in this SDG.

The samples were collected by Tetra Tech NUS on February 4, 2003 and analyzed by Mitkem Corporation laboratory of Warwick, Rhode Island.

All analyses were conducted using EPA SW-846 Method 9045C for pH and ASTM Method D422 for Grain Size.

SUMMARY

All parameters were successfully analyzed in all samples. The findings offered in this report are based upon a general review of all available data including data completeness, laboratory duplicate precision, field duplicate precision, logbook documentation, and calculations.

NOTES

The Relative Percent Difference (RPD) for the laboratory duplicate results for pH were within the quality control limit of 20%.

The Relative Percent Difference (RPD) for the field duplicate results for pH were within the quality control limit of 50%.

EXECUTIVE SUMMARY

Laboratory Performance: None.

Other Factors Affecting Data Quality: None.

The data for these analyses were reviewed to evaluate usability with reference to the EPA "Functional Guidelines for Evaluating Inorganic Analyses ", as amended for use within EPA Region 3 (4/93), and the NFESC document entitled "Navy IRCDQM" (9/99).

The text of this report has been formatted to address only those problem areas affecting data quality.

"I attest that the data referenced herein were reviewed according to the agreed upon validation criteria as specified in the NFESC Guidelines and the Quality Assurance Project Plan (QAPP)."

- J - Analyte detected below quantitation limits
- B - Analyte detected in the associated Method Blank
- * - Value exceeds Maximum Contaminant Level
- S - Spike Recovery outside accepted recovery limits
- R - RPD outside accepted recovery limits
- E - Value above quantitation range
- RL - Reporting Limit

Mitkem Corporation

Date: *25-Feb-03*

CLIENT:	Tetra Tech NUS, Inc.	**Client Sample ID:**	FTASS106
Lab Order:	B0199	**Tag Number:**	FTA-SS-106
Project:	Wallops Island	**Collection Date:**	2/4/03 9:10:00 AM
Lab ID:	B0199-08A		

Analyses	Result	RL	Qual	Units	DF	Date Analyzed
SOIL AND WASTE PH		**SW9045C_S**				
pH	5.8	1.0		pH Units	1	02/06/03 0:00

Qualifiers:

- ND - Not Detected at the Reporting Limit
- J - Analyte detected below quantitation limits
- B - Analyte detected in the associated Method Blank
- * - Value exceeds Maximum Contaminant Level
- S - Spike Recovery outside accepted recovery limits
- R - RPD outside accepted recovery limits
- E - Value above quantitation range
- RL - Reporting Limit
