# Altitude Wind Tunnel/Space Power Chambers

## Historic Facilities at NASA Glenn

When constructed in the early 1940s, the Altitude Wind Tunnel (AWT) was the nation's only wind tunnel capable of studying full-scale engines under realistic flight conditions. It played a significant role in the development of the first U.S. jet engines as well as technologies such as the afterburner and variable-area nozzle. In the late 1950s, the tunnel's interior components were removed so that hardware for Project Mercury could be tested in altitude conditions. In 1961, a portion of the tunnel was converted into one of the country's first large vacuum tanks and renamed the Space Power Chambers (SPC). SPC was used extensively throughout the 1960s for the Centaur rocket program.

### AWT Control Room

## Interactive History

### Multimedia Presentation

This award-winning multimedia piece allows one to interactively learn about the AWT facility and the research conducted there. The piece contains a chronological history of the AWT from its construction and testing of early jet engines during World War II, through the space programs of the 1960s, and to its final use as the Microwave Systems Laboratory. In all, there are over 200 photographs and video clips, including a 1961 NASA documentary on the AWT. Also included are layouts with corresponding images of the facility in different configurations. Links to over 70 related reports and publications are provided, as well.

## Panoramic Views of the Altitude Wind Tunnel

Click photo areas below to view a Quicktime virtual reality view of that location as it appeared during final photographic surveys of the AWT in 2005 and 2007. The highlighted sections are scheduled for demolition in 2008.

**Please note:** Quicktime virtual reality is not supported on 64-bit Windows platform.

## Book

A massive, but little-known, facility in Cleveland, Ohio, played a vital role in the U.S. development of jets, in the training of NASA's first astronauts, and in making NASA's first missions beyond Earth orbit possible. Probes that sent back the first closeup views of the Moon, Mars, Jupiter, and Venus were launched by rockets perfected in the facility. *Revolutionary Atmosphere* tells the story of this obscure giant.

Bob Arrighi followed clues from hundreds of technical reports, letters, books, oral histories, and photographs, and conducted more than a dozen interviews in crafting *Revolutionary Atmosphere* (PDF, 13.4MB). Then he illustrated the story with hundreds of interesting old photographs unearthed from the archives. Arrighi skillfully weaves the history of the facility with the stories of people who created it, modified it, worked in it, solved problems in it, and made history with it. From testimonies about determined leaders like Abe Silverstein and Ray Sharp, to tales of discouraging failures and creative solutions, to anecdotes of model makers and mechanics, readers will find themselves drawn into what life was like working in this revolutionary atmosphere.

## Documentary

*A Tunnel Through Time: The History of NASA's Altitude Wind Tunnel* by Robert S. Arrighi and James Polaczynski (NASA SP-2010-4609) tells the story of an important, but little-known, facility at NASA's Glenn Research Center. This wind tunnel complex played a vital role in the U.S. development of jets, in the training of NASA's first astronauts, and in NASA's first missions beyond Earth orbit. Abe Silverstein's career,

which paralleled much of the AWT's, is highlighted throughout. This video includes a wealth of newly discovered footage, animations demonstrating how the facilities worked, and 3-D imagery.

If you would like a copy of this DVD, please contact the NASA Glenn History Office ([NASA Glenn History Office](#)).

## Historic American Engineering Report

Historic American Engineering Report (HAER) documentation of the Altitude Wind Tunnel and Space Power Chambers to be submitted by the National Park Service to the Library of Congress. The report details the physical history of the site, event history of the facility, contemporary facilities, and architectural and operational descriptions of the facilities and their support buildings. Includes numerous photographs, blueprints, and drawings.

## Facility Description

NACA Lewis Altitude Wind Tunnel

**Altitude Wind Tunnel:** NACA engineers devised a number of ingenious features for the Altitude Wind Tunnel (AWT) to overcome the difficulties associated with operating engines in simulated altitude conditions. These features included a unique steel shell, an air scoop, a make-up air system, and specially designed banks of cooling coils.

[Click for full description](#)

**Space Power Chambers:** Between 1959 and 1963 the facility was slowly converted from a wind tunnel into two test chambers: one a large area that created altitude conditions similar to those produced during the tunnel years and the other, a smaller chamber, which was significantly modified to create a space environment. The facility was renamed the Space Power Chambers (SPC) in September 1962.

[Click for full description](#)

**Support Buildings:** The AWT complex incorporated several external buildings, which were vital to the operation of the facility. These included the Office and Shop Building, Refrigeration Building, Exhauster Building, and others. The tunnel's cooling system was the largest of its kind in the world and considered one of Willis Carrier's most significant accomplishments.

## Altitude Wind Tunnel

When it was built in the early 1940s, the Altitude Wind Tunnel (AWT) was among the most complex wind tunnels ever designed. Its large size allowed the testing of full-scale engines instead of trying to replicate engine behavior in small models. It was also the first to create altitude conditions in which to study engine performance under flight conditions. The ability to control altitude conditions while modifying engines was particularly important during the early development of the turbojet. In order to accomplish these tasks, NACA engineers at the Langley and newly completed Ames laboratories developed several components for the AWT that had not been previously used.

### AWT Schematic

## Tunnel Components

**Tunnel Shell:** The AWT's shell had to be specially designed to withstand external pressure when the tunnel was evacuated and to endure the low temperatures of the high altitudes without becoming brittle.

[Click for full description](#)

**Airflow:** The AWT drive fan could produce wind speeds up to 500 mph. Because engines were being run in the tunnel, the airflow had to be constantly purged and replenished with cool, clean air.

[Click for full description](#)

**Altitude Simulation:** The most complex aspect of the AWT's operation was the simulation of altitude conditions. A massive exhauster system was built to thin the air and a refrigeration system that was unrivaled in the world was designed to produce the low temperatures.

[Click for full description](#)

**Test Chamber:** The 20-foot-diameter test section was one of the largest in the country. It contained an intricate balance chamber to measure the engine's behavior and supply lines to run the engines. The control room used to run the aircraft engines and the tunnel was adjacent to the test section.

## Altitude Wind Tunnel

# Tunnel Shell

The overall shape of the Altitude Wind Tunnel (AWT) was similar to several other contemporary wind tunnels of the National Advisory Committee for Aeronautics, such as the 19-Foot Pressure Tunnel at Langley Memorial Laboratory and the 16-Foot High Speed Wind Tunnel at the Ames Aeronautical Laboratory. The AWT's internal pressure and temperature levels; however, required new methods of designing the tunnel's steel shell.

The tunnel itself was a massive rectangular structure, which for years provided one of the highest vantage points on the Laboratory. The tunnel was 263 feet long on the north and south legs and 121 feet long on the east and west sides. The larger west end of the tunnel was 51 feet in diameter throughout. The east side of the tunnel was 31 feet in diameter at the southeast corner and 27 feet in diameter at the northeast. The throat section, which connected the northwest corner to the test section in the middle of the long northern leg, narrowed sharply from 51 to 20 feet in diameter.

## Altitude Wind Tunnel

## Foundations

### AWT Foundations

**Foundations:** The tunnel was braced by a large elliptical support ring in each corner, the Shop and Office Building's test chamber in the middle, and a series of 120 support rings, which lined the tunnel at 6 foot intervals. Eight of these support rings and the four larger corner rings were anchored to concrete and steel piers which elevated the tunnel. Unique steel rollers were used to bear the tunnel shell in a way that allowed the shell to contract and expand during the tunnel's dramatic temperature and pressure fluctuations. One row of five of the 22-inch-long and 4-inch-diameter rollers was stacked perpendicularly on a second row of five rollers. The rollers were placed between the concrete piers and the support ring buttresses.

### Construction

### H-Shaped Support

### NE Corner of AWT

## Shell

**Shell:** A team of engineers at the NACA's new Ames Aeronautical

Laboratory were responsible for designing the AWT's distinctive shell in 1941 and 1942. The shell consisted of two steel layers with a blanket of insulation between. The inner steel layer was the primary tunnel structure. Its 1-inch-thick steel could withstand external pressure when the tunnel was evacuated to high-altitude pressure levels. A T-1 steel alloy with three times the strength of normal carbon steel was used so that the shell could endure the low temperatures of the high altitudes without becoming brittle.

A 4-inch layer of glass wool was installed with steel mesh over the inner tunnel shell to retain the tunnel's low temperatures. The outer 1/8-inch steel shell was then constructed over this to protect the protection from the environment.

## Inner and Outer Shells

Wide End of AWT

Fiberglass Install

## Roof

AWT Roof with Walkway

**Roof:** By the mid-1940s, a series of stairs, ladders, and platforms were built on the roof of the tunnel. Access was provided by doorways off the east and west sides of the second floor of the test chamber in the Shop and Office Building. Stairs led to the top of the west end of the tunnel. The walkway, interrupted only by the four corner rings, followed the top of the tunnel until ending at the west side of the test chamber.

Steel-grated platforms replaced the original wooden platforms by mid-1945. An elaborate catwalk system would be added to the east end after the Space Power Chamber dome was added in 1963.

## Altitude Wind Tunnel

## Airflow

The Altitude Wind Tunnel (AWT) could produce wind speeds up to 500 miles per hour through its large 20-foot-diameter test section at the standard operating altitude of 30,000 feet. The average speed at lower altitudes was 345 miles per hour. The airflow was created by a large fan near the southeast corner. Elliptical panels of turning vanes were installed in each corner to guide and even the airstream. The tunnel contracted from a diameter of 51 feet to just 20 feet as it approached the test section. This contraction accelerated the air velocity as it passed the engine studied. Contamination from the engine exhaust had to be removed to maintain the altitude conditions and replenished with clean air while the tunnel was running.

## AWT Drive Fan

## Drive Fan

### New Set of Blades

**Drive Fan:** A 12-bladed 31-foot-diameter spruce wood fan as used to create the airflow. The fan was driven at 410 revolutions per minute by an 18,000-horsepower General Electric induction motor that was located in the rear corner of the Exhauster Building. An extension shaft, sealed in the tunnel's shell with flexible couplings that allowed for the movement of the shell, connected the motor to the fan. A bronze screen secured to the turning vanes protected the fan against damage from failed engine parts sailing through the tunnel. Despite this screen the blades did become worn or cracked over time and had to be replaced. An entire new fan was installed in 1951.

### Deterioration of Fan

### AWT Drive System

### Turning Vanes

## Airscoop

**Airscoop:** A unique airscoop was installed immediately downstream from the test section to collect combustion byproducts as they were exhausted by the engines being tested. This scoop, which resembled an aircraft engine nacelle, was held at the center of the tunnel by a vertical support. Compressors in the nearby Exhauster Building drew the vented air out of the tunnel and discharged it into the atmosphere. It was estimated that this scoop would remove 40 percent of the engine exhaust and that a 6000-pound per minute exchange of air would produce a 95 percent clean

## Airscoop Downstream

airflow. In 1951, a large exhaust-gas cooler was installed underneath this section of the tunnel to improve the system.

Compressor

Airscoop Upgrade

J57 With Airscoop

## Make-Up Air

Air Directed to Inlet

**Make-Up Air:** A make-up air system was developed to replenish the air removed by the air scoop. Air from the atmosphere was drawn into a large air dryer located outside the tunnel's southwest corner. The dryer removed condensation from the air to prevent shocks to the tunnel's airflow. After the air was initially cooled in the building's primary coils, its moisture was absorbed by activated alumina beds in the dryer. The air temperature was reduced to the final desired level with a second set of cooling coils. This processed air was introduced into the tunnel through two portals in the western tunnel wall. One of the nozzles extended well into the tunnel and piped the new air directly through the test section. Later this pipe was extended and attached to the engine inlets to increase the tunnel's capacity.

## Altitude Wind Tunnel

# Altitude Simulation

The two primary aspects of altitude simulation are the reduction of the air pressure and the decrease of temperature. This was accomplished through the Altitude Wind Tunnel's (AWT's) large exhaustor and refrigeration systems. These were vital components to the AWT's operation and set it apart from other wind tunnels. The tunnel was originally designed for temperature altitude simulation of up to 30,000 feet and pressure altitude simulation of 45,000 feet. This capacity was increased over the years and reached 100,000 feet by the mid-1950s.

## AWT Control Room

## Cooling Systems

### Cooling Coils in AWT

**Cooling System:** NACA engineers were having a difficult time developing a method of cooling the massive airflow in the AWT to levels necessary for the desired altitudes. Pressure was on to complete the tunnel for use during World War II, and Willis Carrier, who's Carrier Corporation had pioneered the refrigeration industry, took on the AWT project. After several months of studies, the Carrier engineers devised a cooling system that was the largest of its kind in the world. Carrier later referred to the AWT as his greatest achievement. The system could lower the tunnel's temperature to  $-47^{\circ}\text{F}$ , and it was claimed that if used for other purposes it could generate 10,000 tons of ice per day.

The cooling system was powered by 14 Carrier compressors, which were housed in the Refrigeration Building to the west of the tunnel. The compressors converted the freon 12 refrigerant into a liquid. The refrigerant was then pumped into the eight identical banks of cooling coils inside the

tunnel's return leg. These coils were a collection of 260 copper-plated coils arranged in a zigzag design that covered a 51-foot width of the tunnel. The freon absorbed heat as the air passed through the coils. The heat was transferred to the cooling water and sent to the cooling tower where it was dissipated into the atmosphere. At its original capacity, 20,000 gallons of cooling water were required for the system every minute.

### Refrigeration System

### Cooling Tower No. 1

### Cooling System

## Exhaust System

**Exhaust System:** In addition to removing contaminated air through the airscoop,

the exhaust system was used to reduce the air pressure to create the thin atmosphere found at high altitudes. The Exhauster Building directly to the east of the tunnel housed four 1750-horsepower exhausters. These pumped the air out of the tunnel and expelled it into the atmosphere.

The Exhauster Building pumps could originally only handle two-thirds of the 6000 pounds of air per minute required by the AWT, so the system was complemented by the Roots-Connersville centrifugal compressors in the Engine Research Building's basement. The original configuration could simulate altitudes up to 45,000 feet. Most tests were conducted over a range of altitudes beginning as low as 10,000 feet and increasing incrementally to 35,000 feet.

As part of a larger AWT modernization program in 1951, the exhaust system was overhauled. The Exhauster Building was expanded with more powerful compressors, an exhaust gas cooler installed under the airscoop, and circulating water pump house built. In 1957, the Propulsion System Laboratory's Central Air and Exhauster Building, which began operating in 1952 was linked to the exhaust system AWT and Engine Research Building systems. The result for the AWT was an improvement from 12 to 7 pounds per second at 50,000 feet and 66 to 51 at 28,000 feet.

### Altitude Wind Tunnel

## Test Chamber

The size of the Altitude Wind Tunnel (AWT) test section was driven by the desire to test full-scale engines. The 3000-horsepower piston engines, which were larger than those in use in the early 1940s, would require a 20-foot-diameter and 40-foot-long test area to operate with all their components. The engine or test article was installed inside the test section on balances beneath the test section and on the wingtip fixtures. Six balances were housed in the sealed chamber and connected to supports from the tunnel floor or at the wingtips on the walls. These control the position of the engine and are used to record data.

### Engine in Test Section

## Control Room

### AWT Control Panel

**Control Room:** The soundproof control room was used to operate the tunnel and control the engine being run in the test section. The AWT operators worked with assistants in the Exhauster Building and Refrigeration Building to manage the large systems. Although the configuration of the control panels changed frequently, the principal wall contained the make-up air, drive fan, and engine controls. It also included two sets of pneumatic levers that operated different facets of the engine. The other wall was used to manage the combustion, refrigerated and cooling air, and the exhauster systems.

The control room was modified several times, including a large overhaul in 1951. In the early 1960s, when the facility was converted into two test chambers, the control room was used to operate the large altitude tank known as Space Power Chamber No. 2. The facility was not used during the late 1970s and 1980s. The control room was cannibalized and eventually used as a storage room.

### Test Damage

### AWT Control Panel

### Room in 2007

## Test Section

**Test Section:** At 40 feet in length and 20 feet in diameter, the AWT's test section was one of the largest in the country at the time of its construction. Aircraft engines were prepared in the AWT shop, and then lifted by an overhead crane through the high-bay and the second-story test chamber before being lowered into the test section. Technicians

Republic YP-47M

then spent days or weeks hooking up the supply lines and data recording telemetry.

The engines were mounted on wingspans that stretched across the test section. The wingtips attached to the balance frame's trunnions, which could adjust the angle of attack. The balance frame included six measurement devices that recorded data and controlled the engine. The measurements were visible in banks of manometer boards next to the control room. Photographs recorded the pressure levels in the manometer tubes and "computers" manually converted the data into useful measurements.

Manometer Boards

Test Section

Pressure Rake

## Test Chamber

Viewing Platform

**Test Chamber:** The test section, control room, and balance chamber were located in a three-story test chamber in the rear of the Shop and Office Building. The control room, fan room, and manometer boards were located on the mezzanine level next to the test section. The upper level was a large open space, approximately 50 feet high, with the test section sunken up to its midpoint in the floor. This main level contained a large, open wooden viewing platform with stairs built so that people could get from one side of the test section to the other.

A mechanical pulley system was used to raise and lower the tunnel's large clamshell lid into place. The lid was sealed into place using hand-turned locks accessible from the viewing platform. The lid had viewing windows above and below the test article, which permitted the filming and visual inspection of the tests.

## Space Power Chambers (SPC)

During the rush of the early space era, the Altitude Wind Tunnel (AWT) was used for several rocket engine tests. In 1959 several of the tunnel's internal components were removed from the west end of the tunnel so that a series of Project Mercury tests could be conducted inside that area. The tests were successful, but the removal of two sets of turning vanes, cooling coils, and make-up air valves, ensured the facility would not be used again as a wind tunnel.

In 1961, NASA Lewis management decided to convert the facility into two large test chambers and later renamed it the Space Power Chambers (SPC). The conversion, which took over 2 years included removing the tunnel's drive fan, exhaust scoop, and turning vanes from the east end and inserting bulkheads to seal off the new chambers within the tunnel. These chambers were used for a variety of tests on the Centaur second-stage rocket until the early 1970s.

### SPC Drawing

### SPC Components

**Space Power Chamber No. 1:** The eastern section of the tunnel, SPC No. 1, became a vacuum chamber capable of simulating 100 miles altitude. Although other investigations were conducted in the tank, its primary purpose was testing the Centaur rocket's electronics in a space environment.

[Click for full description](#)

**Centaur Setup:** Soon after completing the SPC in 1962, NASA Lewis assumed control of the Centaur Program. The new vacuum chamber would be used to study the Centaur, but it would require an extensive installation of test equipment to create a space environment.

[Click for full description](#)

**Space Power Chamber No. 2:** SPC No. 2 occupied the entire south leg, the west leg, and the throat section of the former tunnel. This large chamber could simulate altitudes of 100,000 feet. It was used for shroud separation and propellant management studies.

[Click for full description](#)

**Control Rooms:** A new control room, which was designed to replicate a launch pad control room, was built underneath the tunnel's test section for SPC No. 1. SPC No. 2 used the former AWT control room to operate its tests.

## Space Power Chambers

### Chamber No. 1

The Space Power Chamber (SPC) No. 1 was among the first wave of large vacuum chambers capable of simulating a space environment. Initial spaceflights during the late 1950s and early 1960s showed the behavior of engines, flight systems, and hardware was affected by the conditions encountered in space. Although larger chambers would later be constructed, the rapid conversion of the Altitude Wind Tunnel (AWT) into a space tank allowed the SPC to play a vital role in the early years of the space program.

The 100-foot-long SPC No. 1 was created in the east leg of the tunnel, which was 31 feet in diameter at one end and 27 feet in diameter at the other. The chamber was used to conduct a series of long-term systems tests on a full-scale Centaur and nose cone separation tests for multiple Surveyor missions. In the 1970s, the new Space Power Facility at Plum Brook Station would supersede the SPC's capabilities.

### SPC No. 1 Setup

## Conversion to Test Chambers

### Conversion

**Conversion to Test Chambers:** The conversion of the AWT into two test chambers was a major undertaking. The actual clearing of the tunnel interior was fairly simple. The turning vanes, cooling coils, and make-up air pipes had been removed in 1959. The drive fan and its assembly, along with the remaining turning vanes, were removed in 1961. After the tunnel was clear, large oval bulkheads were inserted before and after the test section with another near the southeast corner. These effectively created two distinct chambers. Control rooms were installed and a pump house with new vacuum pumps was built underneath the chamber.

Since SPC No. 1 would have to be capable of reaching extremely low pressure levels, the tunnel shell around that area had to be checked for leaks. After the removal of the outer shell and insulation, it was determined that the entire section of the tunnel would have to be rewelded to maintain the required seal. It was felt that the poor work of the original welders was due to the rush to complete the facility during World War II. The necessary repairs were performed for SPC and the shell maintained its seal throughout its tests. The facility was considered ready in September 1962, but the acquisition of the Centaur Program necessitated the addition of a dome and other equipment, which would require another year to complete.

### Insertion of Bulkhead

### SPC No. 1 Bulkhead

### Removal of Vanes

## Vacuum Pump House

**Vacuum Pump House:** The vacuum system was the primary element in SPC No. 1's ability to create a space environment. During the conversion

Vacuum Pump House

of the tunnel to a space tank, the pumping system was replaced by a new oil diffusion-based system, which could create a 10 to the -5 mm of mercury pressure level. Ten diffusion pumps and several roughing pumps were installed in the new Vacuum Pump House building underneath the SPC No. 1. Access ports in the chamber's floor connected directly to the pumps in the building below.

The vacuum was brought down slowly in several phases to prevent excessive airflow over the pumps. The center's central exhaust system could evacuate the SPC to 100,000 feet pressure altitude in about 15 minutes. Then two piston pumps simultaneously removed 12.5 cubic feet of air per second during the roughing stage. A rotary positive displacement pump pulls additional air at 500 cubic feet per second. The final vacuum is pulled down by the ten 32-inch-diameter oil diffusion pumps, which could remove 17,650 cubic feet of air per second.

Construction

Vacuum Port

Pump House in 2007

## Removable Dome

### Inspection of Dome

**Removable Dome:** NASA researchers wanted to be able to stand the Centaur rocket up vertically inside SPC No. 1 so it was decided to add an extension to the chamber's roof and cap it with a removable dome. After a year of additional construction, the new dome was completed in September 1963 and became the facility's distinctive feature.

The extension provided a 45-foot vertical area in which to stand up the Centaur. An elevated catwalk was erected around the dome to allow access to the instrumentation portals and cable trays. The 22.5-foot-diameter lid could be removed using a crane so that the Centaur or other test articles could be lowered into the chamber. Smaller items and personnel could enter through a 15-foot-diameter doorway in one of the bulkheads.

## Space Power Chambers

### Chamber No. 2

Space Power Chamber (SPC) No. 2 was the larger of the two chambers in the former Altitude Wind Tunnel (AWT). It consisted of the entire southern and western legs of the tunnel, as well as the throat section. SPC No. 2 was used for several different Orbiting Astronomical Observatory shroud jettison tests, liquid-hydrogen venting studies, and other investigations.

Unlike the vacuum tank in SPC No. 1, SPC No. 2 did not require a major overhaul to be used as a high-altitude test chamber. In 1959, NASA Lewis management had decided to use this area for several tests for the Project Mercury Program. The existing AWT exhausters and refrigeration systems were powerful enough to achieve the desired altitudes up to 100,000 feet. During the conversion to the SPC, this chamber only required the two bulkheads that sealed it off, some upgraded crane equipment, and a new coat of paint.

#### SPC No. 2

## Project Mercury

### Escape Rocket Test

**Project Mercury Setup:** The AWT's turning vanes and make-up air pipes were extricated from the western section of the tunnel creating a large 121-foot long, 51-foot-diameter chamber, which simulated altitudes of the upper atmosphere. An elevated walkway and banks of lights were erected along the western wall. In this chamber, four test setups were erected between September 1959 and March 1960. The first was the Multi-Axis Spin Test Inertial Facility (MASTIF) that included three cages that pivoted, or "gimbaled," on a stand near the tunnel's throat section. A two-level walkway around the rig and a stairway rising into the throat were built so that researchers could operate and observe the rig. The MASTIF was initially used to calibrate the guidance system for Big Joe, the first full-size Mercury capsule launched. It was modified afterwards with the addition of a pilot's chair, control stick, and display panel to train the Mercury 7 astronauts. The astronauts, along with several test pilots, were asked to bring the spinning rig under control.

In another investigation, a mockup capsule was mounted on the floor near the center of the western leg so that its retrorockets could be fired in altitude conditions. Similarly, a rig was set up near the southwest corner that allowed the jettisoning of a capsule from model Atlas and Redstone boosters. The final Mercury tests were of another capsule model outfitted with its escape rocket tower. This was mounted off one of the elevated make-up air portals so the escape rockets could be fired.

MASTIF

Thrust Stand

Separation Facility

## Space Power Chamber No. 2

**Space Power Chamber No. 2:** SPC No. 2 was sealed off from the other chamber by a 31-foot bulkhead near the southeast corner and from the tunnel test section by a 20-foot-diameter bulkhead in the throat section, which effectively created a large J-shaped chamber. The long south leg was not utilized as a test area, but the western section and the area just before the throat were used extensively.

The catwalk along the western wall provided access to lighting and cameras used to record the tests. An overhead crane was installed over the chamber to permit the transfer of large test articles. The 51-foot-high chamber allowed the vertical erection of full-scale rocket shrouds so that the jettison systems could be tested at high altitudes. It also was long enough that a mass model Atlas/Centaur rocket could be placed horizontally in the chamber so that its retrorockets could be tested.

## 

Contraction Area

Atlas/Centaur Test

Interior of SPC No. 2

## 

### 

**Test Equipment:** Like the Project Mercury tests, the studies conducted during the 1960s in SPC No. 2 required the installation of test equipment for varying lengths of time. These would be removed after the tests, but remnants remained permanently mounted inside the chamber. The first involved apparatus for separation tests of an Atlas/Centaur mass model in September 1963. A trolley system that used the overhead crane, landing gear-type wheels, and a large net to catch the jettisoned Atlas was installed.

In order to work on the tall Orbiting Astronomical Observatory shrouds, in 1965 an oval platform elevator was built on two vertical steel girders. The elevator could be raised the entire length of the chamber, and its 11-foot-diameter opening allowed it to be placed around payload shrouds to assist in test preparations. In late 1965 a scale version of the new Zero Gravity Facility was built inside the chamber, so engineers could analyze the performance of several types of deceleration pellets. Items were dropped through a penetration in the chamber roof into a 5-foot-diameter and over 20-foot-tall deceleration stand that was mounted to the chamber floor.

## Space Power Chambers

### Control Rooms

The new Space Power Chambers (SPC) facility had separate control rooms for each of its two test chambers. SPC No. 2, which used much of the Altitude Wind Tunnel's (AWT's) existing infrastructure, was logically located in the wind tunnel's former control room. The new SPC No. 1 vacuum tank; however, used a new pumping system and possessed additional features. It would be operated from a new control room underneath the former tunnel test section.

During the 1960s the former tunnel test chamber would no longer be needed. It was permanently modified in the early 1960s and used as a workroom and storage area. The facility's shop area continued to be used to prepare test articles for their test runs, but was also used as a setup area for tests in other facilities. Several rooms in the office wing were combined to create larger offices. These were increasingly used by groups of individuals other than just the SPC test engineers.

### SPC No. 2 Control Room

### SPC No. 1 Control Room

#### SPC No. 1 Data Recorders

**SPC No. 1 Control Room:** A new control room for SPC No. 1 was constructed underneath the former tunnel test section. Efforts were made to make this control room as much like the Centaur launch controls at Cape Canaveral as possible. The eastern wall contained the primary controls including Centaur pressure and tanking controls; hydrogen peroxide, hydraulic, stretch, pneumatic, and canister purge systems; and the cold wall and vacuum systems and solar simulator temperature monitor. The northern section consisted of monitors for temperature, pressure, and the solar simulator. The western wall controlled the guidance system, nose cone, and tank vents. The southern section had data and event recorders, radiofrequency and range safety monitors. Racks in the center of the room contained the test conductor and engine controls, ground programmer, a vehicle power monitor, and data recorders.

#### Construction

#### Event Monitors

#### Vacuum Controls

### SPC No. 2 Control Room

**SPC No. 2 Control Room:** The former AWT control room next to the test section was converted into the control room for the tests in SPC No. 2. This primarily involved rewiring the telemetry and updated the control panels. The floor-mounted pneumatic engine controls were also removed.

### General Dynamics Team

The original acoustic tiles on the walls and ceiling remained, as did the overhead fluorescent light fixtures.

The eastern panel controlled the exhaust flow from SPC No. 2, SPC No. 1, the Propulsion Systems Laboratory, Engine Research Building, and the cooler. These areas were laid out schematically on the panel with toggle switches and indicator lights. The next panel operated the liquid nitrogen system. The panel at the west end contained a large number of controls for cameras inside SPC No. 2.

SPC No. 2 Controls

SPC No. 2 Controls

Panel Wiring

## Test Chamber

### Viewing Platform in Former AWT

**Test Chamber:** Since the tunnel's test section no longer needed to be enclosed, the large clamshell lid was removed. Flat, steel grating was installed in the bottom of the test section and a pedestrian bridge was built over the 20-foot-wide gap. A new rail crane was installed in the tunnel between the test section and bulkhead so the test articles could be transported into SPC No. 1. The surrounding test chamber room was used as a workarea for mechanics in the 1960s and storage area in recent years.

The high-bay was converted into the Microwave Systems Laboratory in the early 1980s to study the large near-field antennas. The high section of the shop area is now being used as an acoustical test bay to test large microwave antennas. Forty-foot-tall U-shaped walls covered with row after row of acoustical foam pyramids were built to absorb any microwave rays that escaped the antenna to provide a more precise test atmosphere. In 1983 the high-bay was sealed off from the rear test section area.

## Space Power Chambers

### Centaur Test Setup

With the transfer of the Centaur second-stage rocket program to NASA Lewis Research Center in October 1962, the newly completed Space Power Chambers (SPC) facility had to be modified to accommodate the space vehicle. The chamber was originally designed, but never used, to test satellites, SNAP-8 generators, and smaller space vehicles. The new configuration would take almost a year to complete.

The goal of the test engineers was to subject the Centaur to long durations in conditions that would replicate those encountered during its missions in space. The only elements not replicated were microgravity and meteorites. Other than firing the engines, every aspect of a typical Centaur flight would be performed in SPC No. 1. The most drastic modification was the addition of the dome and detachable lid to the SPC No. 1 chamber, but also included the installation of other elements to simulate the temperatures of space, general setup, work equipment, and infrastructure to power and operate the spacecraft.

### Centaur in SPC No. 1

## Centaur 6A Rocket

### Centaur Into SPC

**Centaur 6A Rocket:** A Centaur second-stage rocket was obtained in the late summer of 1963 and flown to NASA Lewis. After several months of studying the rocket in the SPC shop area and installing the Atlas/Centaur-4 electronics packages, the rocket was lowered into SPC No. 1 by crane. Inside the chamber, the delicate Centaur rested on a horizontal stand and was held in place vertically by stretch towers.

Centaur was a unique space vehicle for several reasons, including its ability to restart its engines in space, its use of liquid hydrogen as a propellant, and its thin inflatable fuel tanks. The 28.5-foot-long and 10-foot-diameter Centaur 6A was powered by two 15,000-pound Pratt & Whitney RL-10 engines, which rotated to steer the rocket when the engine fired. The electronics and control systems were at the forward section of the rocket, while the mechanical and propulsion systems were near the rear.

### Centaur in Shop

### Centaur Stand

### Centaur Display

## Coldness and Radiation of Space

**Coldness and Radiation of Space:** SPC No. 1 was already capable of creating the vacuum of space, but the test engineers also wanted to simulate the cryogenic temperatures and solar radiation found in space. A large copper cold wall with its interior coated with heat-absorbing black paint was created specifically for these tests and assembled around the Centaur. The 42-foot-high wall had vertical ribs filled with liquid nitrogen which produced the low temperatures. The liquid nitrogen was stored in three 7000 gallon tanks stored outside of the chamber, and its pressurization was managed remotely from the SPC control room.

Six panels of 500-watt tungsten-iodine lamps were arranged around the Centaur to simulate the effect of the Sun's heat on the rocket performance. Four of these arrays were on the upper end of the Centaur, and two were located near the RL-10 engines. Certain lamps could be turned on at different times to recreate the changing areas of the rocket exposed sunlight during a mission.

## Top of Cold Wall

Centaur Cold Wall

Cold Wall Diagram

Quartz Lamps

## Centaur Systems

RL-10 in SPC No.1

**Centaur Systems:** The actual setup of the Centaur included a pneumatic system to keep the thin fuel tanks pressurized so that they would not collapse, a hydraulic system to rotate or "gimbal" the RL-10 engines as they would be during flight, and a liquid hydrogen pumping system to fill the propellant tank.

The telemetry for these tests included a high-powered system for powered flight, a lower-power system for coast periods, camera and data transmission systems to view the liquid hydrogen tank, and ground support equipment that controlled and monitored the operation of the Centaur. The instrumentation included 200 transducers, 18 landlines were to record the data in the offsite receiving station, a number of K-logger chart recording systems, and a television camera, which was mounted near the lower section of the Centaur.

## Support Buildings

The Altitude Wind Tunnel (AWT) facility comprised a number of components, which allowed the tunnel to study aircraft engines in an altitude environment. Although integrated into the AWT, these components were housed in large out-buildings. The system was so complex that it was claimed that its design required more effort than the Hoover Dam.

The AWT infrastructure was powerful enough to also run several small supersonic wind tunnels, cool the Icing Research Tunnel, and prepare engines for tests in other facilities. The AWT required large amounts of power to run, so it was only operated at night. When it came online in 1944, the press reported that a single run used more electricity than the city of Columbus, Ohio. The AWT's elimination of test flights and the reduction of development time for new engines quickly compensated for this investment.

### AWT Complex

## Tunnel Components

**Shop and Office Building:** The Shop and Office Building was the heart of the AWT facility. It contained the test section, control room, and instrumentation, as well as a large shop area, three-story high-bay, and two-floor office wing.  
[Click for full description](#)

**Refrigeration Buildings:** The Refrigeration Building housed the Carrier Corporation's large cooling system. It was integrated with Cooling Tower No. 1, which was used to dissipate the heat that the system removed from inside the tunnel, and the Air Dryer Building, which cooled new air before it was added to the AWT's stream.  
[Click for full description](#)

**Exhauster Buildings:** The Exhauster Building and its annex contained the compressors, which removed air from inside the AWT to simulate high altitudes. The building also stored the motor that spun the tunnel's drive fan. A water pump house was added in 1951 to improve the system.  
[Click for full description](#)

**Small Wind Tunnels:** The AWT's exhauster and make-up air systems were used to created the Center's first supersonic wind tunnels. Beginning in 1945, three small supersonic tunnels were built off the AWT's southwest corner and another was created in the AWT's basement.

## Support Buildings

# Shop and Office Building

The Altitude Wind Tunnel's (AWT) Shop and Office Building was used to perform all the functions related to the facility's studies. The T-shaped building was used to prep the engine or rocket component, to operate both the facility and test article, to record and gather data from the tests, coordinate research projects, and, most importantly, to run the engine in the tunnel's test section.

The Shop and Office Building, constructed by the Sam W. Emerson Company in 1942 and 1943, was designed in the same architectural style as the other original buildings at the Laboratory. The building is currently named the Microwave Systems Laboratory. The shop and high-bay areas house the Lab's Near Field Antenna Facility, and the office wing is used primarily by the Educational Programs Office.

[Overview of Shop and Office Building](#)

## AWT at Night

## Shop Area

### Blades in Shop

**Shop Area:** The shop area is an open two-story room that occupies the entire western wing of the Shop and Office Building and opens up into the high-bay in the center of the building. The shop was used to build and disassemble engines before and after their test runs in the AWT. The engines or other test articles were brought through the truck entrance at the front of the high-bay and set in the shop. Technicians worked with the researchers to install proper instrumentation and ready the engine to be run in the tunnel. This often took weeks to accomplish.

Several tests that did not require the tunnel were conducted in this shop area. These included the Mercury Evaporating Condensing Analysis (MECA), electric motor vehicle studies, and antenna testing. In 1991, the shop and high-bay were expanded for additional antenna testing capabilities.

### AWT Staff

### Shop Area

### Electric Vehicles

## High-Bay

**High-Bay:** A three-story high-bay area was used to transport test articles between the shop area and the test section on the second floor in the back of the building. When its turn to run in the tunnel came up, the engine was lifted by the overhead crane from the shop to the high-bay. A 10-ton overhead box crane carried it to the

## Test in High-Bay

test chamber on the second floor in the rear of the building and there it was lowered into the tunnel's test section.

Originally there were no walls between the high-bay and the shop or the upper level of the test chamber. The high-bay was converted into the Microwave Systems Laboratory in the early 1980s, and the bay began being used as an acoustical chamber to test large microwave antennas. In 1983, a 36-foot-high U-shaped wall was built that completely segregated the bay from of the test section area. The facility continues to be used today.

Framework

Wartime Display

Former Test Chamber

## Office Wing

### Researchers in Office

**Office Wing:** The eastern wing of the Shop and Office Building consisted of two floors of office space. This area was physically segregated from the rest of the building and similar to other office areas around the Laboratory. Originally, the rooms were used by AWT personnel. Members of the educational services staff have used the area since the 1970s.

Several first floor offices were enlarged during the 1960s. In 1973 and 1974 the Office and Shop Building underwent a major rehabilitation. The offices were modernized for the first time since they were built in the 1940s. This wing has not changed much since that project.

## Support Buildings

# AWT Refrigeration

The Refrigeration Building located just to the west of the Altitude Wind tunnel (AWT) contained the primary components of the tunnel's cooling system, which was the largest in the world. The Sam W. Emerson Company built the actual building during 1943, but the unique refrigeration system contained within was developed by the Carrier Corporation.

A cooling tower behind the Refrigeration Building was used to expel heat accumulated in the circulating water. A water pump house was added in 1951 to use refrigerated water to cool the gases exhausted through the airscoop. Both the Refrigeration Building and Cooling Tower No. 1 continue to be used today by the Icing Research Tunnel.

## Carrier Compressors

## Refrigeration Building

### Refrigeration Building

**Refrigeration Building:** The Refrigeration Building contains 14 Carrier-designed centrifugal compressors and a flash cooler. The interior of the building is largely open, but there is a small control room along the wall. The 1500-horsepower compressors are aligned in pairs with the cylindrical flash cooler running between them.

There are also three 1500-horsepower York compressors that were used to chill the cooling coils in the Air Dryer Building. These compressors supply chill water for office air conditioning. The chill water is distributed by an underground system of pipes to most of the buildings within the central campus at Lewis Field. Approximately 30 different pipes run between the Refrigeration Building and the AWT, which connect the flash cooler to the heat exchangers in the tunnel.

### Construction

### Electrical Panels

### Refrigeration Building in 2005

## Cooling Tower No. 1

**Cooling Tower No. 1:** Cooling Tower No. 1 is a narrow rectangular structure with settling pools off to its side. Cooling Tower No. 1 was originally a wooden structure with eight cells. In 1951, an additional cell

## Settling Ponds

was added to each end of the tower. In the mid-1950s it could pump 63,000 gallons per minute. In the mid-1980s, Cooling Tower No. 1 was largely rebuilt with all of the cells rehabbed and the wood replaced by composite material. It is still used by the Icing Research Tunnel.

The heat-laden water circulated from the AWT was pumped to the top of the cooling tower. The water was distributed across the cooling tower and sprayed down into the 600,000-gallon basin at the bottom. Sixteen fans in the roof drew air upwards, removing energy from the heat-laden water, and expelling the heat energy into the atmosphere. It then flowed outside into one of the three settling ponds where it cooled further before being recirculated back into the Refrigeration Building.

In 1951, an additional cell was added to each end of the tower. In the mid-1950s it could pump 63,000 gallons per minute. In the mid-1980s, Cooling Tower No.1 was largely rebuilt with all of the cells rehabbed and the wood replaced by composite material. It is still used by the Icing Research Tunnel.

Cooling Tower in 2005

Aerial View

Cooling Tower in 1951

## Pump House

### Water Pump House

**Circulating Water Pump House:** As part of the 1951 AWT modernization project, a pump house was built underneath the northeast leg of the tunnel. This Circulating Water Pump House drew cooling water to be used by the new exhaust system. The water was circulated through in an exhaust gas cooler tank which was used to reduce the temperature of the air exhausted from inside the tunnel.

The pump house contained four Ingersoll Rand pumps, two 250-horsepower discharge pumps, two 300-horsepower spray pumps, and a 75-horsepower spray pump. These drew water through underground lines from the Cooling Tower. The pumps were removed in the 1960s and the structure has been used as a storage area. It was demolished along with the tunnel in 2008.

## Support Buildings

# Exhauster Building

The Exhauster Building was located just to the east of the Altitude Wind Tunnel (AWT). This building served two crucial roles for the wind tunnel—it housed the drive motor that operated the tunnel's fan, and it contained the exhausters and compressors that evacuated the tunnel to simulate the pressures at altitude. It also replaced some of the contamination with fresh air. The building was constructed by the Sam W. Emerson Company in 1943, but experts from the Roots Connersville Company supervised the installation of the exhausters, and General Electric installed the drive motor.

A smaller rectangular addition with new, more powerful exhausters was attached to the northeast corner of the building in 1951. In the 1960s, portions of the original building were used as part of the Solar Power Laboratory. By the mid-1970s the Exhauster Building was converted into a Visitor Center. The large exhauster room is now filled with displays and the annex built in 1951 is a 170-seat assembly room with a stage. A lobby area was created at the nexus of the original building and the annex.

## Exhausters

### Exhauster Building

**Exhausters:** The exhaust system was originally powered by four 4-cylinder 60-inch-bore and 30-inch-stroke Worthington exhausters. These 1750-horsepower pumps were located in the Exhauster Building's large main floor area. These pumps removed the air from inside the tunnel and expelled it into the atmosphere. Following complaints from local residents during the final days of World War II, mufflers were added to the vent pipes to reduce the low-frequency vibrations, which rattled nearby windows.

Three Ingersoll-Rand 8-cylinder reciprocating pumps were installed in a new annex in 1951. The new exhausters significantly increased the system's capacity. In addition, an exhaust gas cooler, pump house, and cooler pit were also installed underneath the tunnel where the exhaust lines exited.

### Exhaust Gas Cooler

### Air-Regulating Panel

### Visitors Center

## Drive Motor

**Drive Motor:** On the first floor of the Exhauster Building, a 31-foot-long, 4200-kilowatt generator was set up in line with a slightly smaller generator. These generators created the power needed to start up the drive motor used to rotate the large fan inside the AWT. Due to the AWT's massive power loads arrangements had to be made with the local power company before operating the tunnel.

A three-level tower was located in the southwest corner of the building to house the drive system. The lower level contained a small generator, and the upper two levels contained the drive motor. The primary drive motor was an 1800-

horsepower, 4000-volt, 2180-amp General Electric induction motor. The drive shaft traveled from the brick tower and into the east wall of the AWT.

Drive Motor

Drive Motor Plate

Generators

## Air Dryer Building

Air Dryer Building

**Air Dryer Building:** The Make-Up Air System was designed to replenish the air in the AWT that was removed by the exhaust scoop. The Air Dryer Building was used to remove condensation from atmospheric air to prevent shocks when introduced to the AWT's airflow. The facility consisted of the air dryer tank and two sets of cooling coils enclosed in a two-story brick building. In 1948 a new air tank was built on top of the existing tank and a new primary coils building built on top of the existing building.

Ambient air entered from the south, then in the primary coils building passed through filters and cooling coils to reduce its temperature to about 40 °F. The air enters the 29-foot-diameter dryer tank where beds of activated alumina absorbed moisture to a dew point of -70 °F. The air then entered the Secondary Cooling Building north of the dryer, which cooled the air to the desired tunnel temperature. The resulting cool, dry air was

pumped to both the AWT and adjacent small supersonic wind tunnels.

## Support Buildings

# Small Wind Tunnels

The emergence of the turbojet during the final years of World War II transformed aviation virtually overnight. The Altitude Wind Tunnel (AWT), which had been designed for the piston engine, was quickly adapted for the jet engine. The future would be supersonic wind tunnels, though, and during the summer of 1945 the Lab's Wind Tunnel Division Chief Abe Silverstein designed several small wind tunnels that would use the AWT's powerful exhauster system to create supersonic speeds. One building behind the AWT contained three of these tunnels stacked vertically. Another supersonic tunnel was created in the AWT's basement.

## Stack Tunnels

### Small Supersonic Tunnels

**Stack Tunnels:** Three small supersonic wind tunnels built in 1945, 1949, and 1951 were housed in an L-shaped building directly behind the southwest corner of the AWT. The first tunnel was built in just 90 days. The airflow for the tunnels was supplied by the AWT's make-up air line. After passing through one of the test sections, the exhaust line tied directly into the AWT's south wall.

The control room and manometers were located in the building's basement. Early tests in the first tunnel focused on supersonic diffusers, supersonic ramjets, and supersonic aerodynamics. Tests run in the late 1950s included inlet studies for North American, light gas-injection wing burning, high-altitude rocket ignition for NASA, NASA noise studies, and drogue parachute configurations. The tunnels were deactivated in 1961 as the Center concentrated on space programs. The tunnels were finally demolished in the 1980s.

Ramjet in Small Tunnel

Stack Tunnel Aerial

Construction

## Duct Lab

**Duct Lab:** In a tunnel between the basements of the AWT's Shop and Office Building and the Engine Research Building, a supersonic wind tunnel with an 8-foot-long, 4-inch-wide, and 10-inch-high test section was built in 1945. Like the Stack Tunnels, the Duct Lab took advantage of the AWT's exhaust system to produce its speeds of Mach 1.6 to 5.0 and temperatures of 400 °F. Schlieren and laser anemometry systems are used to obtain flow visualization measurements.

Although the AWT has been idle for over 30 years, operation of the Duct Lab continues. In recent years it has been used for development of supersonic injectors, artificial intelligence methods, nonintrusive laser

## Timelines

# Events (1936 to 1957)

### 1936

Fifth Volta conference—"High Velocities in Aviation" attended by NACA  
NACA Committee on Aeronautical Facilities formed  
George Lewis begins visit of Germany aeronautical facilities  
NACA Committee on Relation of NACA to National Defense initiated  
First supersonic wind tunnel built at Peenemunde, Germany

### 1938

NACA authorizes study on need for additional research labs  
Wright Brothers Wind Tunnel begins operation at altitudes up to 37,000 feet  
Future Research Facilities Special Committee studies a new NACA lab

### 1939

Congress appropriates \$10 million for new NACA lab  
British Heinkel He178 is first jet aircraft successfully flown  
Moffett Field, California, selected as site for new NACA laboratory  
Charles Lindbergh recommends NACA build an engine research plant  
NACA approves establishment of an engine research lab  
Forming of Committee on New Engine Research Facilities led by George Mead  
Ames Aeronautical Laboratory construction begins at Moffett Field

### 1940

NACA approves scope and estimates for engine lab  
President Roosevelt calls for 50,000 U.S. aircraft per year  
Congress appropriates \$8.4 million for engine research lab  
Italians fly thermal jet Campini-Caproni CC-2  
Four-man NACA board visits Cleveland to assess the land for new engine lab  
Edward Sharp named Chief of Construction Division at Langley Field  
NACA announces selection of Cleveland, Ohio, for new lab

### 1941

Aircraft Engine Research Lab groundbreaking in Cleveland  
NACA Special Committee on Jet Propulsion formed  
First flight of British Gloucester E28/39 with Whittle jet engine  
Edward Sharp arrives to oversee construction of Aircraft Engine Research Laboratory (AERL)  
General Electric given contract to build Whittle engine in United States  
United States enters World War II  
First flight of German Messerschmitt Me262 jet fighter

### 1942

Hangar becomes first completed building at AERL  
Carrier Corporation wins contract for AWT refrigeration system  
Formal initiation of research at AERL  
General Hap Arnold requests AERL construction be given Class 1 priority  
Construction of AWT begins  
Messerschmitt ME 262 becomes first operational jet aircraft  
First flight of German V-2 rocket at Peenemunde  
First atomic chain reaction at University of Chicago  
Dr. Sharp appointed AERL manager

### 1943

Elliptical corner rings erected for AWT  
Westinghouse 19A is first U.S.-designed jet engine  
Installation of AWT drive motor and flash cooler  
GE I-16 turbojet engine secretly tested in Jet Propulsion Static Lab  
Abe Silverstein transfers from Langley to Cleveland

### 1944

AWT becomes operational

AWT tests first jet engine in United States and B-29's R-3350 engine  
General Henry "Hap" Arnold visits AERL  
Icing Research Tunnel begins operation

**1945**

Japan surrenders ending World War II  
Major reorganization of AERL to focus on jet engines  
Modified AWT to muffle low-frequency vibrations  
George Lewis suffers two heart attacks  
Construction on 8- by 6-Foot Supersonic Wind Tunnel begun

**1946**

First successful U.S. operation of afterburner in AWT

**1947**

AERL renamed Flight Propulsion Research Laboratory  
First supersonic flight by Chuck Yeager in X-1  
AWT Fan and Tunnel Survey  
Lab renamed the Lewis Flight Propulsion Laboratory

**1948**

8- by 6-Foot Supersonic Wind Tunnel begins operation

**1949**

Abe Silverstein becomes Director of Research  
Research divisions reorganized for supersonic flight

**1951**

AWT undergoes major upgrade and modernization

**1952**

Propulsion Systems Laboratory begins operation  
Korean War begins

**1953**

AWT reduced hours of operation due to modernization project  
Air Force's Propulsion Wind Tunnel begins operation

**1955**

10- by 10-Foot Supersonic Wind Tunnel completed  
Harold Kaufman conducted tests in AWT for Project Bee  
Walter Olsen issues paper on future rocket propulsion research

**1957**

Sputnik I launched  
Rockets discussed at NACA Lewis tri-annual inspection  
B-57 flies on liquid hydrogen for Project Bee

## Historical Research

A great deal of information has been collected regarding the Altitude Wind Tunnel(AWT). This includes materials created during the recent documentation of the facility, as well as records, publications, and reports generated during the facility's operating years. In addition, there are many NASA historical publications that are excellent sources of contextual history.

**Timelines:** These pages include timelines of testing in both the AWT and Space Power Chamber. They also include a general timeline of events that influenced the history of the facility.

[Events Timeline \(1936 to 1957\)](#)

[Events Timeline \(1958 to 2008\)](#)

[Tests Timeline \(1944 to 1975\)](#)

**AWT Documents:** Here one can find transcriptions and PDFs of original documents, articles, reports, and speeches. [These materials](#) span from World War II through Project Mercury and the 1960's space program.

## Additional Research Materials

Additional materials describing the AWT and the studies conducted there are available in the [Interactive History](#) portion of this Web site. These include a chronological history of the facility, links to research reports and other AWT-related publications, a 9-minute documentary video created by NASA in 1961, and much more.

# Events (1958 to 2009)

### 1958

NACA Lewis incorporated into the new NASA space agency  
AWT shut down for tunnel leak test; end of use as a wind tunnel

### 1959

Big Joe Mercury capsule mock-up tests in AWT  
Big Joe boilerplate capsule launched  
Lewis tasked with five Project Mercury tasks  
Interior of west end of AWT gutted for Mercury tests

### 1960

Mercury astronauts train in MASTIF rig in AWT  
Mercury escape tower tests  
Mercury-Redstone 1 launch failure

### 1961

Yuri Gagarin becomes first human in space  
Alan Sheppard becomes first American in space  
Abe Silverstein returns to Lewis as Center Director  
Conversion of AWT to the Space Power Chambers (SPC) begins

### 1962

First Centaur (F-1) launch fails  
Surveyor program substitutes Centaur for Agena rocket  
AWT renamed the SPC  
Centaur Program transferred to NASA Lewis

### 1963

Agena Program transferred to NASA Lewis  
Installation of dome on SPC No. 1  
Atlas/Centaur separation test rig arrive at NASA Lewis  
Erection of Centaur yoke in SPC  
Atlas/Centaur separation tests are first SPC tests  
Centaur rocket arrives at NASA Lewis  
Atlas/Centaur-2 successfully launched

### 1964

Centaur rocket inserted into SPC No. 1  
Cleveland Parade of Progress Exposition features NASA  
Surveyor model launched on Atlas/Centaur-4  
Atlas/Centaur-5 explodes on launch pad

### 1965

Atlas/Centaur-6 launches successfully

## Mitigation Project

### Rusting AWT in 2005

In 2005, NASA Glenn proposed to remove the entire Altitude Wind Tunnel (AWT) circuit except for the test section. The AWT was unique based on its sheer size alone, but the maintenance costs for the idle facility rivaled that of the Center's largest research programs. Although not used since the mid-1970s, this facility has a rich history and played an important role in both NASA and aerospace history. NASA Glenn felt it important to document the facility as thoroughly as possible prior to its destruction.

[Ohio Historic Inventory Form](#) (PDF 6.1MB)

[Demolition Article](#) (PDF 5.1MB)

**Description of Mitigation:** This Web site is part of a wider effort to document the history of the AWT. This project was formally begun in May 2005 after the finalization of Statement of Work 6.31 for the NASA Glenn History Office. The project includes the gathering of records, images, films, oral histories, and information on the facility, its tests, and significance. The information is being distributed to the public through a number of methods including a historical publication, documentary video, and this Web site. [Read More...](#)

**Demolition Process:** It was decided in early 2005 to remove the tunnel portion of the AWT from the NASA Glenn campus. Preparations for the demolition work began in early 2008. The demolition itself began in the fall. [Read More...](#)

**Public Awareness Meeting:** On April 27, 2006, a community awareness meeting was held at NASA Glenn to alert the public of the Center's plans to remove the AWT and Propulsion Systems Laboratory 1 and 2. Speakers discussed the scope of the demolition, environmental issues, the history of the facilities, and the historical mitigation project. [Read More...](#)

## Mitigation

# Community Awareness Meeting

On April 27, 2006, NASA Glenn Research Center invited the public and NASA employees to a meeting to learn more about NASA's plans to demolish the Altitude Wind Tunnel and the Propulsion Systems Laboratory 1 and 2. The attendees learned details about the proposed demolitions, the history of the facilities, efforts underway to document the facilities, and the results of the environmental impact studies conducted for the projects.

In accordance with the National Preservation Act, the meeting allowed attendees to ask questions and voice any opposition to the projects. The presentations were videotaped, and copies can be obtained by contacting the NASA Glenn History Office at [history@grc.nasa.gov](mailto:history@grc.nasa.gov). The PowerPoint slides, which combine the text of the talks with historic photographs and charts can be viewed below.

### Mitigation

## Historical Mitigation Effort

Section 106 of the National Historic Preservation Act requires that Federal agencies document their historic facilities before any significant structural changes, demolitions, or relocations. NASA Glenn Research Center has a number of historic facilities, some of which are scheduled to be demolished. The NASA Glenn History Program, Preservation Officer, and facility managers have worked with the Ohio State Historic Preservation Officer to develop strategies, budgets, and work plans to record the history of these facilities.

The result will be a permanent documentary record for the facility, lessons learned insight for internal NASA use, increased public awareness of NASA Glenn contributions to society, educational resources, and a collected body of materials for future researchers. The Altitude Wind Tunnel project consists of two facets—the documentation and preservation of the facility's history and the interpretation and dissemination of that information to the public.

### Meeting With Ohio SHPO

### Documentation

**Documentation:** The documentation includes the collection of documents from the Glenn Records Management holdings, other NASA centers, retirees, and other sources and the scanning and captioning of over a thousand negatives, digitizing historic films. In addition, a thorough photographic survey, including virtual reality panoramic images, of the facility was performed. A large effort was undertaken to research the history of the facility through these records, existing reports, oral histories, and other sources.

**Dissemination:** The information that was collected is in the process of being distilled into several different products to be shared with the public and NASA employees. These include this Web site, a book describing the facility's history, a three-part construction document to physically describe the facility, a video documentary, display panels, and an Ohio historical marker.

### Mitigation

## Demolition of the Altitude Wind Tunnel

In 2003, for the first time in its history, NASA Headquarters allocated funds for the demolition of unused facilities and asked its centers to submit lists for consideration. NASA Glenn proposed the removal of nine buildings, including the Altitude Wind Tunnel (AWT). Minor exterior repairs and repainting of the AWT were estimated in 2004 to be over \$4.5 million. NASA Headquarters has concurred with Glenn's decision and advocated the proposed demolition.

In preparation for the demolition process, NASA Glenn created a requirements document in September 2004 and a Statement of Work in 2005. The Ohio Historic Preservation Office was notified in May 2004. A Section 106 report was submitted in July 2006 and approved in September 2007. Design services were obtained and demolition plans were created. Bids to perform the work were solicited, and the contract was awarded in 2007.

### AWT Demolition

## Demolition Process

The demolition was performed in three phases: utility relocation, lead paint and asbestos remediation, and the actual demolition of the facility. Some of the AWT utilities were rerouted before the demolition so they could be used by other facilities. A pipe bridge was built behind the AWT and along the back wall of the Icing Research Tunnel for this rerouting. The next step was removal of lead paint from the welds in the tunnel shell where torches would be cutting.

Clearing Tunnel

Pipe Bridge

Paint Removal

Workers on lifting platforms cut along the welds to segment the outer shell. As each steel plate was removed, the insulation underneath was also taken away. Next, the segmenting of the thick inner steel shell ensued. Again, workers with torches were hoisted into place to systematically cut away large sections. The work started in the middle of the tunnel and proceeded to the two ends with their larger corner rings. Pieces of the shell were flattened and laid on the muddy ground to support the large cranes.

First Section

Cutting Inner Shell

Flattened Shell

Auxiliary work included the demolition of the Circulating Water Pump House and Vacuum Pump House underneath the AWT. The generators and drive motor were removed from the Visitor Information Center, the former Exhauster Building.

A wall was demolished to help extract the generator, and the tower roof was removed so a crane could lift the drive motor out. Once outside on the ground, the large equipment was cut into smaller pieces for transportation. The former Shop and Office building (now the Microwave Systems Laboratory, Building 7), which previously housed the tunnel's test section, had its asbestos siding removed and replaced. Seals were placed where the former tunnel entered the building. The final step will be soil remediation, regrading, and paving the site of the former wind tunnel.

## Demolition Team

The NASA Project Team was lead by Bryan J. Coates, P.E. (Project Manager), Patrick Edmonds (Quality Assurance Technician), and Randy Dworznik (Inspector) from the Facilities Management Branch located in the Facilities Division at the Glenn Research Center.

NASA Team

NASA Waste Management

The NASA Waste Management Team performed critical oversight of the waste streams associated with the demolition, completed weekly inspections of the site, and documented all material leaving the site.

This project was awarded to Pinnacle Construction (Prime Contractor). Pinnacle's team consisted of:

Bob Zerbe – Project Manager  
Bill Brown – Site Superintendent  
Jerry Stevens – Site Superintendent  
Lindsey Schweizer – Sky

Pinnacle

Local Operator

For a task of this size, a number of subcontractors were used by Pinnacle Construction. The following is a list of project subcontractors:

Soehlen Piping  
Fowler Electric  
Brandenburg Industrial Service Company  
Norris Brothers Company, Inc.  
Precision Environmental

Soehlen piping performed the utility reroute prior to the start of the tunnel remediation and demolition. Systems involved included 125 psi shop air, steam, steam condensate, and natural gas. Soehlen performed the mechanical isolation and disconnect of these systems.

Fowler Electric performed the electrical isolation and disconnection of all high- and low-voltage electrical equipment associated with the project.

Norris Brothers Company, Inc. removed the large motors and generators from Building 8 and installed the tunnel caps on Building 7.

Norris Brothers

## Brandenburg

**Brandenburg Industrial Service Company** performed the primary task of tunnel remediation and demolition. Mauricio Gonzalez (Foreman) and Rafael Olivencia (Foreman) were responsible for running the demolition crew.

Brandenburg augmented their crew with laborers from the **Local 310** (Laborers' International Union of North America) and an operator from **Local 18** (International Union of Operating Engineers).

**Wind Tunnels:** Almost as long as humans have contemplated air travel, they have sought to create flight conditions in a controlled environment to assist the design process. Today, computer-aided design and flight simulators can replicate flight conditions, but traditionally there were two basic methods for simulating flight with model aircraft on the ground—propelling an aircraft through the air or subjecting a stationary aircraft to an airflow. The earliest simulation tools in the mid-18th century used this first method. These "whirling arms" consisted of a pole with a model aircraft held on an extended arm. The arm was then rotated rapidly in circles to simulate actual flight.

The second, and most successful, form of testing was the placement of a stationary model inside a tunnel. Flight was simulated when air was pulled through the tunnel and past the model aircraft. The tunnel method proved to be more practical and efficient than the whirling arms. The tunnel operator can control wind speed and other atmospheric conditions, as well as the aircraft's angle of attack and attitude. Although there are full-scale wind tunnels in existence, most are not large enough to accommodate an actual aircraft. Instead, scaled-down models, which are comparatively inexpensive and easy to modify, are used.

### Wind Tunnel History

### How Tunnel Works

Select image

### Vacuum Chamber History

Select image

**Vacuum Chambers:** The use of vacuum chambers to simulate high altitudes began during World War I. The air pressure decreases as altitude increases. By reducing the quantity of air in a chamber or tank, one can simulate the air pressures of high altitude. This was done for a variety of aeronautics uses, including studying engine behavior and the effect of altitude on pilots.

### How SPC Works

Select image

Initial space flights during the late 1950s and early 1960s showed the behavior of engines, flight systems, and hardware was affected by the vacuum and cold temperatures found in space. There was a need to test full-size versions of these items in a vacuum chamber before the mission. In the early 1960s there was a wave of large vacuum chambers built for this purpose.

# How the Altitude Wind Tunnel Works

The Altitude Wind Tunnel (AWT) at NASA Glenn Research Center was able to test full-scale aircraft engines in airspeed, altitude, and air quality found during flight. Airspeed up to 500 miles per hour was created by a 31-foot-diameter propeller that was spun by a 18,000-horsepower engine in the Exhauster Building. The airflow was straightened by turning vanes located in the tunnel corners. A powerful cooling system in the Refrigeration Building could reduce the tunnel's temperature to  $-47^{\circ}\text{F}$  as the air passed through accordionlike cooling coils in the wide end of the tunnel.

The Exhauster Building contained large compressors, which removed air from inside the tunnel to create the thin atmosphere found at high altitudes. The engine being tested was installed in the 20-foot-diameter test section and operated remotely from the control room. A myriad of instrumentation recorded the tunnel conditions and engine performance during the tests. The engines exhausted contaminants, which were removed from the tunnel through an airscoop located just beyond the test section. Fresh air was introduced into the windstream prior to the test section to make up for the exhausted air.

## Tunnel Animation

## Glossary

**Open-Loop Tunnel:** Wind tunnels are generally either open- or closed-loop designs. The open-loop type is a simple design that consists of a long open-ended tube. A fan at the far end of the tunnel pulls the air through the tunnel, past the test section, and expels it out the far end of the tunnel. Open-loop tunnels are often inefficient to operate.

**Closed-Loop Tunnel:** The closed-loop tunnel is usually square shaped. It recycles airflow so is more efficient. The closed-loop tunnel is more expensive to build and requires a larger area. Sets of turning vanes are placed in the corners to guide the airflow through the wind tunnel loop. The AWT was a closed-loop tunnel.

**Test Section:** Portion of a wind tunnel where the test article and sensors are placed. The AWT had a large 20-foot-diameter test section.

**Settling Chamber:** Section of a wind tunnel, usually just before the contraction, where the airflow is straightened and turbulence reduced. The AWT had a 51-foot-diameter settling chamber.

**Contraction:** Section prior to the test section where the tunnel narrows to increase the speed of the airflow through the test section. It is sometimes referred to as the throat section. The AWT contracts from 51 to 20 feet in diameter.

**Diffuser:** Area past the test section where the tunnel's diameter widens so that the airspeed is slowed down.

**Drive:** The apparatus that forces air through the tunnel. It is usually a large fan that is powered by a powerful motor. The AWT had a 31-foot-diameter fan spun by an 18,000-horsepower motor.

**Pressure Tunnel:** Small-scale test articles and the atmospheric airflow resulted in questionable test results due to the Reynolds number. By pressurizing the tunnel to altitudes corresponding to the size of the test article, actual flight conditions are simulated.

**Reynolds Number:** Early wind tunnel test results were often inaccurate since the airflow around the tunnel model and the actual flight were different. Osborne Reynolds (1842–1912) discovered that flow over a scale model would only be identical to the full-scale object if the Reynolds number was identical. The Reynolds number is a nondimensional factor that indicates the ratio of the momentum to the viscosity in gas or liquid fluid flow. Basically, the Reynolds number expresses the relationship of the fluid density, velocity, the object's size, and the coefficient of viscosity of the fluid relationship.

# History of Wind Tunnels

Wind tunnels have been used for studying the elements of flight since 1871. Initially they were small-scale, open-loop devices such as the Wright Brothers' tunnel with its 16-inch test section. Wind tunnels grew in size and complexity, particularly after the Ludwig Prandtl first closed-loop tunnel in 1909. Tunnels were built in a variety of sizes and shapes with varying speeds depending on the current technology and their intended areas of study. The Altitude Wind Tunnel (AWT) was the first wind tunnel built to study engine performance in altitude conditions. A list of important wind tunnels is below.

## Timeline of Wind Tunnel Development

# How Space Power Chamber No. 1 Works

Space Power Chamber No. 1 (SPC) at NASA Glenn Research Center was able to create conditions found at 100 miles altitude in order to study spacecraft behavior in outer space. The chamber was connected to the Center's central air system, which could evacuate the chamber to 100,000-foot pressure altitude. This was followed by two piston pumps that further thinned the air. The final vacuum was brought down by 10 oil diffusion pumps located below the chamber.

A complex setup was installed in the chamber that could replicate all aspects of outer space except microgravity and meteors. The cryogenic temperatures of space were supplied by a nitrogen-filled cold wall, which enveloped the spacecraft. Solar radiation was simulated using six banks of quartz lamps. In addition, a hydraulic system rotated the rocket's RL-10 engines as they would during flight. A tanking system used to keep the balloonlike fuel tanks partially filled and a wide array of telemetry was installed. The tests were operated and monitored in a control room that resembled the actual launch pad controls.

## Chamber Animation

Select image to run

## Glossary

**Vacuum:** A space entirely devoid of matter, including air. Outer space has a very low density, which is similar to a vacuum.

**Cold Wall:** A copper baffle, which has liquid-nitrogen-filled ribs and black interior that produced low temperatures found in outer space. The SPC No. 1 cold wall was 20 feet in diameter and 42 feet high and used a thermal siphon to draw cryogenic liquid nitrogen into the vertical ribs.

**Altitude:** Considered the elevation above an acknowledged level. In aerospace situations, this level is usually mean sea level. Height is the elevation above a point on the ground.

**Space Tank:** A chamber from which air is removed. The resulting vacuum is used to simulate the air pressure levels found in outer space. Space tanks, or vacuum chambers, often include other elements, such as cold walls, to further simulate the space environment.

**Atmospheric Pressure:** Pressure caused by the weight of the atmosphere. As the altitude increases, the atmospheric pressure decreases. At sea level it has a mean value of 1 atmosphere.

**Vacuum Pump:** A pump used to remove air from a space or tank. SPC No. 1 used several types of vacuum pumps. The diffusion pumps, which had no moving parts, directed residual molecules from the chamber using high-speed jets of fluid.

# Vacuum Chamber History

The first sustained vacuum was achieved in 1643. The first vacuum pump followed in 1650. As flight began developing in the early 1900s, aeronautical researchers began setting up engines in vacuum test chambers to simulate higher altitudes. As the nation began sending spacecraft into space, the need for test chambers capable of producing a higher level of vacuum was apparent. The Space Power Chamber No. 1 (SPC) was among the first of a wave of large vacuum chambers that emerged in the early 1960s. The Space Power Facility at NASA's Plum Brook Station, which began operation in 1969, is the largest vacuum chamber in the world. A list of vacuum chambers used to simulate altitude is below.

### Gallery

The Gallery contains over 1300 photographs related to the Altitude Wind Tunnel and Space Power Chambers facility, tests, events, and staff. Many of these were recently scanned and are available for the first time.

Clicking a thumbnail will launch an Item Detail page that displays the title, filename, date, and, in most cases, a detailed caption. A high-resolution version of each image is also available from the detail page. After viewing Item Detail, click the Back button on your web browser to return to the Gallery Index pages.

### Gallery

The Gallery contains over 1300 photographs related to the Altitude Wind Tunnel and Space Power Chambers facility, tests, events, and staff. Many of these were recently scanned and are available for the first time.

Clicking a thumbnail will launch an Item Detail page that displays the title, filename, date, and, in most cases, a detailed caption. A high-resolution version of each image is also available from the detail page. After viewing Item Detail, click the Back button on your web browser to return to the Gallery Index pages.

The Gallery contains over 1300 photographs related to the Altitude Wind Tunnel and Space Power Chambers facility, tests, events, and staff. Many of these were recently scanned and are available for the first time.

Clicking a thumbnail will launch an Item Detail page that displays the title, filename, date, and, in most cases, a detailed caption. A high-resolution version of each image is also available from the detail page. After viewing Item Detail, click the Back button on your web browser to return to the Gallery Index pages.

### Gallery

The Gallery contains over 1300 photographs related to the Altitude Wind Tunnel and Space Power Chambers facility, tests, events, and staff. Many of these were recently scanned and are available for the first time.

Clicking a thumbnail will launch an Item Detail page that displays the title, filename, date, and, in most cases, a detailed caption. A high-resolution version of each image is also available from the detail page. After viewing Item Detail, click the Back button on your web browser to return to the Gallery Index pages.
