(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

Notes:

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

Notes:
(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.
(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

Notes:

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

| | | | | | | | | | | | Total of Receptor Risks Across All Media | | | | | Total of Receptor Hazards Across All Media |
| | | | | | | | | | | | -- | | | | | 38 |

Notes:

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

| Notes: | | | | | | | | | | Total of Receptor Risks Across All Media | -- | | | | Total of Receptor Hazards Across All Media | 42 |

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

Notes:

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

| Medium Total | | | | | | | | | | | -- | | | | | 0.3 |
| | | | | | | | | | | | Total of Receptor Risks Across All Media | | | | | Total of Receptor Hazards Across All Media |
| | | | | | | | | | | | -- | | | | | 0.3 |

Notes:

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

| Notes: | | | | | | | | | | | Total of Receptor Risks Across All Media | 7E-05 | | | | Total of Receptor Hazards Across All Media | -- |

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

| Notes: | | | | | | | | | | | Total of Receptor Risks Across All Media | | | | | 7 |

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

| | | | | | | | | | | | Total of Receptor Risks Across All Media | | | | | Total of Receptor Hazards Across All Media |
| | | | | | | | | | | | -- | | | | | 3 |

Notes:

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

Table 7-5.DSA
Calculation of Chemical Cancer Risks and Non-Cancer Hazards
Reasonable Maximum Exposure (Data Sensitivity Analysis; Central/Southern)
Future On-Site Hypothetical Resident (Lifetime) - Total Soil, Soil (Outdoor Air), Groundwater (Trench) or (Outdoor Air), Groundwater (Potable Use), Groundwater (Vapor Intrusion)
Remedial Investigation Report
Project 15 CL, Wallops Flight Facility, Wallops Island, VA

Notes:

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

| Notes: | | | | | | | | | | | Total of Receptor Risks Across All Media | | | | | 6 |

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

| | | | | | | | | | Total of Receptor Risks Across All Media | | -- | | | Total of Receptor Hazards Across All Media | | 3 |

Notes:

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

Notes:

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

Notes:

(1) CR and HQs are rounded to one non-zero digit; cumulative totals may be slightly higher or lower depending on degree of rounding.

(2) Cancer risk is only presented for the lifetime receptor, whereas non-cancer hazard is calculated separately for the child and adult receptor.

# 0. Executive Summary

An Ecological Risk Assessment (ERA) was conducted for the National Aeronautics and Space Administration (NASA) Goddard Space Flight Center's Wallops Flight Facility (WFF; Contract No. 80KSC019D0010) Main Base located near Chincoteague, Virginia. (**Figure 1-1**).

The primary purpose of the ERA is to identify constituents of potential ecological concern (COPECs) and assess the need and the level of effort necessary to perform further evaluation of the current and future Site risk. The ERA fulfills this purpose by: (1) identifying potential ecological receptors and habitats at the Site; (2) determining which pathways are potentially complete; (3) evaluating if constituents of interest (COIs) present within complete exposure pathways have the potential to pose significant environmental risk; and (4) to determine if this potential for risk warrants additional ecological risk characterization.

The ERA was conducted in accordance with the following federal guidance:

- United States Environmental Protection Agency (USEPA). 1997. *Ecological Risk Assessment Guidance for Superfund* (ERAGS).
- USEPA. 2001. *The Role of Screening-Level Risk Assessments and Refining Contaminants of Concern in Baseline Ecological Risk Assessments.*
- USEPA. 2015a. *EPA Region 3 BTAG – Frequently Asked Questions.* September.
- USEPA. 2018. *Region 4 Ecological Risk Assessment Supplemental Guidance*.

Potential ecological exposure was evaluated under current conditions using recent analytical data collected in relevant exposure media (i.e., surface soil, sediment, surface water, and pore water). Exposures were evaluated for four source areas of concern (AOCs) and several nearby wetland areas potentially impacted by overland flow and groundwater to surface discharge.

The scope of this ERA report includes Steps 1 and 2 of the 8-step ERAGS process (also referred to as a Screening Level Ecological Risk Assessment [SLERA]). Steps 1 and 2 were used to identify COPECs in potentially affected environmental media to support a scientific management decision point (SMDP) regarding the need for further risk characterization and/or remediation. The list of COPECs was refined consistent with the initial stage of a Baseline Ecological Risk Assessment (BERA) Step 3 (referred to as Step 3a COPEC Refinement) to reduce uncertainty in the SLERA Step 1 and 2 conclusions and to refine the recommendations presented in the report by applying more realistic exposure assumptions.

Guided by an ecological conceptual site model (ECSM), a conservative screening evaluation was conducted to assess potential risks related in surface soil (soil macroinvertebrates and terrestrial wildlife) and sediment/surface water/pore water (benthic macroinvertebrates and aquatic/semi-aquatic wildlife). If COIs were detected above wildlife-specific benchmarks, dose rate models (DRMs) were prepared to assess potential adverse effects to selected ecological receptors from incidental and dietary ingestion.

After Step 2 of the SLERA, the results of the risk characterization determined the following SMDPs:

- The information is not adequate to a make a decision at this point and the ecological risk assessment continued to Step 3.
    - All Soil AOCs
        - Surface Soil – results of the direct contact evaluation and wildlife DRMs have indicated potential adverse effects for soil macroinvertebrates and wildlife.
    - Upgradient Drainage
        - Sediment – results of the direct contact evaluation and wildlife DRMs have indicated potential adverse effects for benthic macroinvertebrates and wildlife.
    - Downgradient Estuarine
        - Sediment/Surface Water/Pore Water – results of the direct contact evaluation and wildlife DRMs have indicated potential adverse effects for benthic macroinvertebrates and wildlife.
    - **Table ES-1** includes a summary of COPECs retained for the Step 3a COPEC Refinement within the BERA.

During BERA Step 3a, refinements were made to reduce uncertainty in both the direct contact evaluation and wildlife DRMs. The results for the refined direct contact evaluation (**Table ES-2 and ES-3)** and wildlife DRMs (**Table ES-4**) are summarized below. The results of the SLERA, BERA Step 3a COPEC refinement, and consideration of the uncertainties present in the evaluation support the following SMDPs for WFF:

- “There is adequate information to conclude that ecological risks are negligible and therefore no need for remediation on the basis of ecological risk” (USEPA, 1997)
    - Northern AOC: soil macroinvertebrates and terrestrial wildlife
    - Western AOC: soil macroinvertebrates and terrestrial wildlife
    - Upgradient Drainage: benthic macroinvertebrates and aquatic/semi-aquatic wildlife
- The information indicates a potential for adverse ecological effects
    - Central AOC: soil macroinvertebrates and terrestrial wildlife
    - Southern AOC: soil macroinvertebrates and terrestrial wildlife
    - Downgradient Estuarine: benthic macroinvertebrates and aquatic/semi-aquatic wildlife
        - Impacts to sediment greatest within exposure area – adverse population-level effects to ecological receptors via surface water and pore water are unlikely.

# 1. Introduction

An Ecological Risk Assessment (ERA) was conducted for the National Aeronautics and Space Administration (NASA) Goddard Space Flight Center's Wallops Flight Facility (WFF; Contract No. 80KSC019D0010) Operable Unit 7 (OU7), Project 15 Construction Debris Landfill (CDL) located near Chincoteague, Virginia. (**Figure 1-1**).

The primary purpose of the ERA is to identify constituents of potential ecological concern (COPECs) and assess the need and the level of effort necessary to perform further evaluation of the current and future Site risk. The ERA fulfills this purpose by: (1) identifying potential ecological receptors and habitats at the Site; (2) determining which pathways are potentially complete; (3) evaluating if constituents of interest (COIs) present within complete exposure pathways have the potential to pose significant environmental risk; and (4) to determine if this potential for risk warrants additional ecological risk characterization.

The ERA was conducted in accordance with the following federal guidance:

- United States Environmental Protection Agency (USEPA). 1997. *Ecological Risk Assessment Guidance for Superfund* (ERAGS).
- USEPA. 2001. *The Role of Screening-Level Risk Assessments and Refining Contaminants of Concern in Baseline Ecological Risk Assessments.*
- USEPA. 2015a. *EPA Region 3 BTAG – Frequently Asked Questions.* September.
- USEPA. 2018. *Region 4 Ecological Risk Assessment Supplemental Guidance*.

The ERA was informed primarily by the following documents related to the WFF:

- Versar. 2011. *Final Remedial Investigation Report*. Remedial Investigation of the Construction Debris Landfill NASA Wallops Flight Facility Accomack County, Virginia.
- AECOM 2020. *Supplemental Field Investigation Data Report Revision 2*. Project 15 Construction Debris Landfill Wallops Flight Facility, Wallops Island, Virginia. Contract No. 80KSC019D0010.

Potential ecological exposure was evaluated under current conditions using recent analytical data collected in relevant exposure media (i.e., surface soil, sediment, surface water, and pore water). Exposures were evaluated for four source areas of concern (AOCs) and several nearby wetland areas potentially impacted by overland flow and groundwater to surface discharge.

The scope of this ERA report includes Steps 1 and 2 of the 8-step ERAGS process (also referred to as a Screening Level Ecological Risk Assessment [SLERA]). Steps 1 and 2 were used to identify COPECs in potentially affected environmental media to support a scientific management decision point (SMDP) regarding the need for further risk characterization and/or remediation. The list of COPECs was refined consistent with the initial stage of a Baseline Ecological Risk Assessment (BERA) Step 3 (referred to as Step 3a COPEC Refinement) to reduce uncertainty in the SLERA Step 1 and 2 conclusions and to refine the recommendations presented in the report by applying more realistic exposure assumptions.

The results of the SLERA and BERA Step 3a COPEC Refinement were used to reach one of the following conclusions for this ERA Report:

- There is adequate information to conclude that ecological risks are negligible and therefore no need for remediation on the basis of ecological risk;
- The information is not adequate to make a decision at this point, and the ecological risk assessment process will continue to Step 3; or
- The information indicates a potential for adverse ecological effects, and a more thorough assessment is warranted.

# 2. Step 1: Screening Level Problem Formulation and Ecological Effects Evaluation

The following fundamental components were evaluated as part of Step 1 of the ERA preliminary ecological screening assessment:

- Identify ecological setting and potential habitats
- Identify potential ecological receptors
- Identify constituents known or suspected to exist at the WFF
- Evaluate potential migration pathways that exist at the WFF
- Characterize fate and transport mechanisms
- Describe constituent ecotoxicological properties
- Confirm potentially complete migration pathways and ecological receptors that might exist at the WFF
- Identify assessment and measurement endpoints
- Identify conservative ecological screening benchmarks

## 2.1 Ecological Setting and Potential Habitats

The ecological setting of WFF was characterized using information from the results of the supplemental field investigation (SFI). **Figure 2-1** presents a layout of the WFF. This information was supplemented with resources from the Virginia Department of Environmental Quality (VDEQ), United States Forestry Service (USFS), United States Fish and Wildlife Service's (USFWS's) National Wetlands Inventory (NWI), Natural Resources Conservation Service (NRCS), and aerial imagery. Soils and potential habitats within or near the Site are summarized below.

### 2.1.1 Soils

**Table 2-1** summarizes the soil types occurring in and around the AOCs present at WFF. Based upon online NRCS soil mapping, there are four soil types present within the WFF – Bojac fine sandy loam, 0 to 2 percent (%) slopes, Chincoteague silt loam, 0 to 1% slopes, Magotgha fine sandy loam, 0 to 2% slopes, and Molena loamy sand, 6 to 35% slopes. The Molena loamy sands are the predominant soil type across the WFF with the 6 to 35% slopes covering over 90% of the DUs. The Magotgha fine sandy loams and Chincoteague silt loams are associated with the wetland area found within the CDL boundary which abuts both the AOCs and the nearby Little Mosquito Creek.

NRCS (2020) describes Molena loamy sands as having a high infiltration rate (low runoff potential) when thoroughly wet, and consisting mainly of deep, well drained to excessively drained sands or gravelly sands. These soils have a high rate of water transmission. These soils have a higher permeability and a higher percentage of coarser sands.

The Magotgha fine sandy loams are associated with the tidal wetland areas which exist within the CDL boundary directly to the north and east of the AOCs. Magotgha fine sandy loams typically occur in salt marshes on coastal plains. The parent material consists of marine sediments. Depth to a root restrictive layer is greater than 60 inches. The natural drainage class is poorly drained. Water movement is considered moderately high in the most restrictive layer, and the soil is frequently flooded (NRCS, 2020).

### 2.1.2 Terrestrial Habitats

WFF is located within the Middle Atlantic Coastal Plain Level III Ecoregion, associated with the more general Mississippi Alluvial and Southeast USA Coastal Plains, and Eastern Temperate Forests Level II and Level I Ecoregions, respectively (USEPA, 2013). This ecoregion extends from Delaware to the South Carolina/Georgia border and consists of low elevation flat plains, with many swamps, marshes, and estuaries. Its low terraces, marshes, dunes, barrier islands, and beaches are underlain by unconsolidated sediments. WFF is also classified as the Eastern Shore subregion of the Outer Coastal Plain physiographic province as per the Virginia Department of Conservation and Recreation (VDCR) (Fleming, et. al, 2020). This region is defined by having the state's minimum relief (0m / 0ft, or mean sea level), and elevation does not exceed 18m (60ft). This area is part of a chain of large bay and marsh complexes and barrier islands with both active and stabilized dunes. These islands are dynamic landscapes that are constantly buffeted by powerful winds and waves, generally eroding on the ocean side and accreting on the sound side. The diversity of wetlands in this region spans a range of freshwater to mesohaline, lunar-tidal and wind-tidal estuaries; tidal and palustrine swamps; non-riverine groundwater-saturated flats; seasonally flooded ponds and depressions; seepage-slope wetlands; saturated peatlands; and various tidal and non-tidal aquatic habitats. Forty-six percent of Virginia's Coastal Plain is forested, including 38% of the uplands and 75% of the wetlands (Fleming, et. al, 2020).

The maritime zone of the Outer Coastal Plain is vegetated with a unique suite of pine and hardwood forests, dune woodlands and scrub, dune grasslands, and sparse beach vegetation — communities well adapted to deep sands, periodic salt spray, and oceanic storm impacts. The typical development of maritime vegetation proceeding along a gradient from the beach inland starts with the upper beaches and overwash flats that support a sparse assemblage of *Cakile edentula* (American Sea Rocket), *Salsola kali* (Saltwort), and a few other salt-tolerant, succulent annuals. The most mature maritime forests of the Eastern Shore generally consist of Loblolly Pine in mixtures with *Prunus serotina var. serotina* (Black Cherry) and several oaks. Maritime-zone wetlands include some of the state's rarest natural communities, including sea-level fens, interdune ponds and wet grasslands, and maritime swamp forests (Fleming, et. al, 2020).

### 2.1.3 Aquatic and Semi-Aquatic Habitats

Bounded on the north and east by Little Mosquito Creek, Simoneaston Bay to the east, and Wattsville Branch to the west, WFF sits just above mean sea level (amsl) at 20 to 30 feet amsl. Additionally, a narrow creek channel that parallels the larger Mosquito Creek bounds the site on the east. The National Wetlands Inventory (NWI) mapper classifies the aquatic and semi-aquatic habitats as Estuarine and Marine Deepwater (E1UBL), which consists of deep-water tidal

habitats and adjacent tidal wetlands that are usually semi-enclosed by land but have open, partly obstructed, or sporadic access to the open ocean, and in which ocean water is at least occasionally diluted by freshwater runoff from the land. The salinity may be periodically increased above that of the open ocean by evaporation. Along some low-energy coastlines, there is appreciable dilution of sea water.

Offshore areas with typical estuarine plants and animals, such as red mangroves (Rhizophora mangle) and eastern oysters (Crassostrea virginica), are also included in the Estuarine System. The substrate in these habitats is continuously covered with tidal water (i.e., located below extreme low water) (NFWS, 2020a). Estuarine water regimes and water chemistry are affected by one or more of the following forces: oceanic tides, precipitation, freshwater runoff from land areas, evaporation, and wind. Estuarine salinities range from hyperhaline to oligohaline. These Estuarine Systems include both estuaries and lagoons. It is more strongly influenced by its association with land than is the Marine System. In terms of wave action, estuaries are generally considered to be low-energy systems (Cowardin et.al, 1979).

Deepwater Marine Habitats are permanently flooded lands lying below the deepwater boundary of wetlands. Deepwater habitats include environments where surface water is permanent and often deep, so that water, rather than air, is the principal medium within which the dominant organisms live, whether or not they are attached to the substrate. As in wetlands, the dominant plants are hydrophytes; however, the substrates are considered nonsoil because the water is too deep to support emergent vegetation (U.S. Soil Conservation Service, Soil Survey Staff 1975). The VDCR defines this area as part of the Marine System Natural Community which includes Upper Beaches and Overwash Flats.

### 2.1.4 Wetland Habitats

In general terms, wetlands are lands where saturation with water is the dominant factor determining the nature of substrate development and the types of plant and animal communities living in the substrate and on its surface. Unlike the aquatic Estuarine and Marine Deepwater habitats, most wetland substrates also qualify as “soil” (FGDC, 2013). Wetlands and deepwater habitats are defined separately because traditionally the term wetlands have not included deep, permanent water; however, both must be considered in any investigation. This transitional area is critical to defining potential exposure pathways for both aquatic and terrestrial receptors.

The NWI map overlay for the area of the WFF indicate that both tidal and non-tidal wetlands occur at the site. There are three predominant kinds of wetlands at WFF, including marine, estuarine, and palustrine wetlands. The NWI map indicates many large areas of estuarine wetlands adjacent to the main base, with several smaller parcels of palustrine forested wetlands (USFWS, 2020a). The Estuarine Systems, which cover more than 100 acres of land near the WFF site including the areas of natural deposition from the site AOC’s are classified by the NWI as Estuarine and Marine Wetland (E2EM1N), which are similarly described as the aquatic habitats in the previous subsection but with important distinctions which make it unique.

### 2.1.5 Critical and Sensitive Habitats

No federal critical habitats are located within the direct vicinity of the WFF (USFWS, 2020b and 2020c). Sensitive habitats on and adjacent to the WFF include the Chincoteague National

Wildlife Refuge and the Assateague Island National Seashore to the immediate north, and the Wallops Island National Wildlife Refuge which borders the main base to the west. These refuges are federal and state protected areas for both migratory and nonmigratory wildlife. Other sensitive habitats at the WFF include habitat for federally listed threatened and endangered species and wetlands as well as estuarine habitats such as Mosquito Creek, Chincoteague Bay, and Hog Creek.

Although no specific habitat was identified within or near the WFF, the VDCR National Heritage Database Search (https://vanhde.org/species-search ) indicated that listed threatened species and species of concern (Loggerhead (Sea Turtle) [Caretta *caretta*]) and migratory birds (Saltmarsh Sparrow [Ammospiza *caudacuta*], Piping Plover [Charadrius *melodus*], and Peregrine Falcon [Falco *peregrinus*]) have large ranges that may overlap the WFF (VDCR, 2020). A thorough review of threatened and endangered (T&E) species is provided in **Section 2.2.2**.

## 2.2 Potential Ecological Receptors

Potential ecological receptors that might be expected to occur throughout the WFF were identified using habitat type and species information published in literature. This information was supported by state resources published by the VDCR, such as *Virginia Natural Heritage Data Explorer* (VDCR, 2020). The sections below include both commonly occurring wildlife and a review of sensitive habitats and applicable T&E species.

### 2.2.1 Commonly Occurring Wildlife

Groups of commonly occurring wildlife include soil macroinvertebrates, amphibians and reptiles, birds, and mammals. Wildlife likely to be encountered within or near the WFF are briefly discussed below:

- Soil and benthic macroinvertebrates
    - Soil macroinvertebrates can occupy any portion of the WFF with a defined soil layer. Common terrestrial soil macroinvertebrates include macrofauna such as earthworms, woodlice, millipedes, and beetles; mesofauna including springtails, mites, and potworms; and microfauna such as nematodes.
- Benthic macroinvertebrates could occur within the any of the aquatic and semiaquatic habitats within the WFF (i.e., Little Mosquito Creek, drainage channels or tributaries, wetlands, and areas which are ponded or frequently flooded). Common benthic macroinvertebrates include freshwater snails, crustaceans, beetles, and larval stages of many emergent aquatic insects (i.e., midges, dragonflies, damselflies, mosquitoes, blackflies, and mayflies).
- Amphibians and reptiles
    - The wooded areas, scrub, marshes, and wetlands within the WFF may provide habitat such as damp leaf litter, moist crevices within trees, fallen trees or logs, submerged structures, and/or banks that may be used by reptiles and amphibians.

  - Commonly occurring reptiles and amphibians may include the green tree frog (*Hyla cinerea*), bullfrog (*Rana catesbeiana*), southern leopard frog (*Rana sphenocephala*), red back salamander (*Plethodon cinereus*), eastern hog-nosed snake (*Heterodon platyrhinos*), northern brownsnake (*Storeria dekayi dekayi*), northern water snake (*Nerodia sipedon sipedon*), ring-necked snake (*Diadophis punctatus*), spotted turtle (*Clemmys guttata*), eastern box turtle (*Terrapene carolina carolina*), eastern mud turtle (*Kinosternon subrubrum subrubrum*), common snapping turtle (*Chelydra serpentina serpentine*), atlantic green sea turtle (C*helonia mydas mydas*), atlantic ridley sea turtle (*Leidochelys Kempi*), leatherback sea turtle (*Dermochelys coriacea*), atlantic hawksbill sea turtle (*Eretmochelys imbricata*), and five-lined skink (*Eumeces fasciatus*).

- Birds
  - Birds most likely to be found within the WFF would make use of open grass/shrub areas, and/or nearby forested/shrub wetlands. Additionally, predatory birds may use tall canopy trees to hunt small birds and mammals feeding within the WFF.
  - Commonly occurring birds may include American kestrel (*Falco sparverius*), black and white warbler (*Mniotilta varia*), common grackle (Quiscalus *quiscula*), red-tailed hawk (*Buteo jamaicensis*), turkey vulture (*Cathartes aura*), brown-headed cowbird (*Molothrus ater*), American crow (*Corvus brachyrhynchos*), downy woodpecker (*Picoides pubescens*), eastern bluebird (*Sialis sialis*), and American robin (*Turdus migratorius*).

- Mammals
  - Common interior forest and mixed woodland species would likely enter the WFF and feed on ground vegetation/shrubs, soil invertebrates, and small mammals. Aquatic and semi-aquatic species would likely feed on vegetation or macroinvertebrates within the adjacent wetland areas.
  - Commonly occurring species may include white-tailed deer (*Odocoileus virginianus*), Virginia Oppossum (*Didelphis Virginiana*), red fox (*Vulpes vulpes*), raccoon (*Procyon Lotor*), eastern cottontail (*Sylvilagus Floridanus*), meadow jumping mouse (*Zapus Hudsonius*), meadow vole (*Microyus Pennsylvanicus*), eastern gray squirrel (*Sciurus carolinensis*), muskrat (*Ondatra Zibethicus*) and little brown bat (*Myotis Lucifugus*).

### 2.2.2 Threatened and Endangered Species

Both federal (USFWS, 2020c) and VDCR (https://vanhde.org/species-search) resources were queried to identify T&E species. Species listed by these sources are provided in **Table 2-2**. Rationale for the potential to occur at the WFF was supplemented by NatureServe Explorer (http://explorer.natureserve.org/index.htm).

## 2.3 Potential Source Areas and Constituents of Interest

Because of historic Department of Defense actions at or surrounding the WFF CDL, the primary COIs are metals associated with former training activities, VOCs, SVOCs, and Dioxins/Furans associated with former dumping and burning activities. The subsections below summarize the historical context of the WFF and findings of the previous RI field investigation (Versar, 2011).

### 2.3.1 Facility History

The site ownership and use, as summarized from the final RI (Versar, 2011), is presented in this section. Prior to development of the Site by the U.S. government, the current WFF property was farmland and marshland. The Department of Navy acquired the property in 1942 and established a World War II training facility, the Naval Auxiliary Air Station, for naval aviators. The original runways and buildings have been modified and extended, as needed, to accommodate the evolving mission of the facility. Accordingly, the WFF property has experienced periods of construction and demolition of runways, buildings, and roadways.

The Navy discontinued naval training operations at the facility in 1959 when NASA took custody of the Main Base as well as the northern portion of Wallops Island and the Mainland; the property transfer was finalized in 1961. From 1959 to 1974, the three areas were known as Wallops Station and were used for support of the Civilian Space Program.

NASA excised approximately 397 acres of the Main Base to the U.S. Fish and Wildlife Service in 1975. The official facility name was changed to Wallops Flight Center that same year. In 1981, Wallops Flight Center was consolidated with Goddard Space Flight Center, and the name of the facility changed again to Wallops Flight Facility. WFF is currently used as a suborbital and orbital rocket launch site to support NASA and other state and federal missions.

### 2.3.2 Current Investigations

As determined by the Final Remedial Investigation Report, Remedial Investigation of the Construction Debris Landfill, NASA Wallops Flight Facility, Accomack County, Virginia (Versar, 2011) and Revised Draft FS (CDM Smith, 2018), additional data collection activities were conducted to provide data required to update the HHRA and ERA and report the changes in HHRA and ERA addenda. The potential source is direct releases to soil, sediment, groundwater, surface water and porewater from past waste disposal activities. A total of four AOCs were evaluated for this ERA and are presented in **Figure 2-1**.

The four areas of concern (AOCs) at the Project 15 CDL (the Site) in the remedial investigation (RI) were identified as and described by the nature of the apparent historical use as follows:

- Northern AOC – Disturbed Ground – This AOC was an area of disturbed ground in 1949 that was an excavation in 1954.
- Central AOC – Mounds of Material – This AOC was an area with several mounds of unidentified material in 1954 and was an excavation by 1959.
- Southern AOC – Burning Dump – This AOC was an area of disturbed ground with two man-made channels; the AOC's use as a burning ground was confirmed on a 1950 site map.

- Western AOC – Shallow Excavation – This AOC is interpreted to be a shallow excavation that is now located inside the runway area fence.

## 2.4 Identification and Evaluation of Migration Pathways

An ecological conceptual site model (ECSM) was developed to depict the source areas, exposure media, and migration pathways used to identify significant exposure pathways for evaluation in the ERA (**Figure 2-2**). The ECSM includes the following information:

- Potential source area(s)
- Potential migration pathways
- Exposure media
- Complete and incomplete exposure pathways for potential ecological receptors via the following exposure routes:
    - Direct contact/absorption
    - Direct or incidental ingestion of substrate
    - Ingestion of prey and plant dietary items

**Potential Source Area(s)**

The four potential source areas have been identified within the WFF including the Northern AOC, Southern AOC, Central AOC, and Western AOC. These areas have been identified by previous and current investigations (Versar, 2011) to have been significantly impacted by historical training and construction debris dumping activities. The source areas are related solely to historical impacts.

**Potential Migration Pathway(s)**

The evaluation and identification of potentially complete migration pathways is one of the primary goals of a screening level ecological risk assessment (USEPA, 1997).

As defined, a “migration pathway” is the pathway by which a constituent travels from a source to receptors. A pathway can involve multiple media such as erosion of soil from upland to wetland areas, or volatilization to the atmosphere. Historical direct releases to soil and subsequent erosion/dissolution into groundwater and transport to the wetland area represent the primary release mechanisms within the WFF.

Migration pathways evaluated within the ERA include:

- Erosion of surface soil
    - Contamination in surface and subsurface soils were confirmed by the RI report (Versar, 2011) at the CDL Site. These constituents present in the soil as a result of burial and burning of debris are subject to physical, biological, and chemical reactions that directly influence their persistence and potential migration.
    - Given the WFF topography and site orientation, stormwater runoff from significant rain events is possible to transport suspended COIs off-Site to the nearby wetland area and Little Mosquito Creek northeast of the AOCs. While the more heavily vegetative area that exists in between the WFF site boundary

and the wetland / Little Mosquito Creek could potentially serve as a barrier to slow the transmission of come contamination, there is still the possibility that COIs could migrate to this wetland area.

- Groundwater discharge
    - Waste materials at the CDL Site were buried and burned on the ground at the Central and Southern AOCs. Their impact to groundwater, therefore, is derived by leaching through soil to groundwater.
    - The unconfined groundwater system flowing beneath the CDL Site discharges at the small man-made drainage channels and the tidal channel of Little Mosquito Creek that forms the eastern boundary of the site. Therefore, the maximum extent of groundwater contamination is defined by this surface water feature.
    - 27 wells have been installed on-site: 17 shallow wells, 4 deep temporary wells, and 6 monitoring wells.
    - Groundwater discharge at the sites indicated above may potentially occur as upwelling within the groundwater-surface water (GW-SW) transitional zone or hyporheic zone (HZ). The USEPA (2008a) defines the GW-SW transition zone as “a region beneath the bottom of a surface-water body where conditions change from a ground-water dominated to surface-water dominated system within the substrate”. The transitional zone also includes the HZ, which represents the interface of groundwater, sediment, sediment pore water, and surface water. USEPA (2008a) defines the HZ as a “latticework of underground habitats through the sediments associated with the interstitial waters in the substrate beneath and adjacent to moving surface-waters.”

## 2.5 Fate and Transport Characteristics

This sub-section discusses constituent fate and transport processes in potentially affected media within or near the WFF.

### 2.5.1 Terrestrial Media

Site-related COIs detected in terrestrial media (i.e., surface soils) include metals (i.e., antimony, copper, lead, and zinc). Within soil, metals can be found in multiple states including dissolved in soil solution, adsorbed on inorganic soil constituents, precipitated as solids, or present in the structure of primary and secondary minerals (Shuman, 1991).

Additionally, the fate and transport of a metal in soil depends significantly on the chemical form and speciation of the metal (USEPA, 1992). Once in the soil, metals are initially adsorbed, and then subjected to adsorption reactions. The adsorption of metals is associated with pH, redox potential, clay content, soil organic matter, iron and manganese oxides, and carbonate content. Adsorption results in metals being transformed into different chemical forms that vary with respect to bioavailability, mobility, and toxicity.

### 2.5.2 Aquatic and Semi-Aquatic Media

Within this ERA, aquatic and semi-aquatic potentially impacted media include groundwater, sediment porewater, surface water, and sediment. While erosion of impacted soils to the adjacent wetland area bordering Little Mosquito Creek is unlikely, groundwater discharge may have introduced COIs within impacted media from source areas within the AOCs to the wetland area.

Metals partition between solid and liquid phases in aquatic and semi-aquatic environments. Partitioning is based on the available ligands and the strength of the potential metal-ligand complexes. The release of metals from solid phases to liquid phases governs the bioavailability and toxicity of metals. Metals are subjected to biogeochemical processes and conditions that influence their partitioning, including the redox state of sediment and pH of the interstitial water. The microbial degradation of organic matter influences redox conditions across the sediment-surface water interface (Baker, 1994; Stumm and Morgan, 1981; Charriau et al., 2011). Generally, metal mobility increases at low pH and decreases as pH increases, at which point greater sorption occurs (USEPA, 2007a).

As a result of this partitioning, the bioavailability and toxicity of metals in aquatic and semi-aquatic media is associated with the exchangeable fraction of metals in the dissolved phase rather than the total phase metal concentration (USEPA, 2007a). The majority of metals in sediment porewater are complexed by colloids, and do not exist as freely dissolved metal-ion complexes (Burgess et al., 1996). Therefore, concentrations of metals measured in filtered porewater samples more accurately represent the dissolved fraction of metals, which is bioavailable and can be incorporated into the tissues of benthic invertebrates, rather than bulk sediment concentrations (USEPA, 2005).

### 2.5.3 Biota

Bioaccumulation represents the potential for a constituent to accumulate in the tissues of an organism. In those instances where bioaccumulation exceeds the ability of an organism to metabolize those constituents, toxic effects can potentially be observed. Wildlife ingesting prey with body burdens of lipophilic compounds may also experience adverse effects when accumulation reaches a threshold level. The purpose of evaluating bioaccumulation potential is to describe the potential of constituents to bioaccumulate in tissues and potentially exert a toxic effect and/or expose upper trophic wildlife receptors through ingestion pathways.

Heavy metals encountered at the WFF, including methylmercury, are known to bioaccumulate and biomagnify (USEPA, 2000). The implications of biomagnification are that even a low concentration of a metal in environmental media or diet items can result in a high enough dosage that adverse effects for birds and mammals may potentially be observed. Metals can bioaccumulate to a point where the concentrations may become a significant source of dietary metal to their predators. Wildlife based screening levels presented in **Section 2.10** of this ERA are protective of potential bioaccumulation.

## 2.6 Ecotoxicological Profiles

This section summarizes the general ecotoxicological effects associated with WFFs COIs including VOCs, SVOCs, pesticides, PCBs, dioxins/furans, cyanide, and metals.

### 2.6.1 Volatile Organic Compounds

Volatile organic compounds (VOCs) are a subcategory of organic compounds with a high vapor pressure at room temperature such as acetone, toluene, benzene, tetrachloroethylene [PCE], trichloroethylene [TCE], vinyl chloride, and xylene. High volatility means that air is the most important environmental media for this group of compounds, and inhalation is likely to be the exposure route of concern (USEPA, 2020a). The relatively high Henry's law constants of site VOCs indicate that they may volatilize from the groundwater into the soil pore space in the unsaturated zone. Once in the soil pore space, VOCs can migrate upward through the soil and discharge to the atmosphere at the ground surface (USEPA, 2005; USEPA, 2007). The health effects from exposure to VOCs vary depending on the particular VOC and the length and route of exposure. Individual VOCs have been associated with impacts to the immune system, hepatic system, blood and fetal development delays (DOE, 2020).

### 2.6.2 Semi-Volatile Organic Compounds

Semi-volatile organic compounds (SVOCs) are a subgroup of VOCs that tend to have a higher molecular weight and higher boiling point temperature. SVOCs encompass a large number of different organic chemicals with unique properties affecting their transport through the environment as well as their toxicity and mode of action. Examples of commonly encountered SVOCs include plasticizers, chlorinated phenols and ploy aromatic hydrocarbons (described further below). The health effects from exposure to SVOCs vary depending on the particular SVOC, the length of exposure, and individual SVOCs have been associated with impacts to the respiratory system, endocrine and thyroid disruption, reproductive toxicity, and development delays (USEPA, 2016a).

#### 2.6.2.1 Polycyclic Aromatic Hydrocarbons (PAHs)

PAHs occur in the environment as complex mixtures (USEPA, 2009a) and are considered Type I narcotic constituents (Verhaar et al., 1992). The predominant mechanism of PAH toxicity to macroinvertebrates is non-polar narcosis, which results in the alteration of cell membrane function and can then result in mild toxic effects or mortality depending upon the duration and intensity of the exposure (USEPA, 2009a). The potential effects of PAH-induced narcosis on benthic invertebrate communities can include decreased abundance, diversity, and growth (Environment Canada, 1999). Typically, PAHs adsorb readily to organic material and fine particles in soil, and most have very low solubility. When released to soil, these compounds will adhere to the soil particles and may be transported through surface runoff to sediment in water bodies. A small percentage may dissolve and percolate to groundwater.

### 2.6.3 Pesticides

Pesticides are used to prevent, destroy, repel, or mitigate pests including insects, mice and other animals, weeds, or fungi as well as to kill organisms that can cause diseases such as bacteria and viruses. These products contain both active ingredients and inactive, or inert, ingredients and may include organic or inorganic components. There are a large number of different pesticide formulations with unique properties affecting their transport through the environment as well as their toxicity and mode of action. Application of pesticides has been

widespread and exposure to environmental receptors may occur through a variety of pathways depending on the specific pesticide used and the attributes of the ecosystem to which it is applied (USEPA, 2020). The health effects from exposure to pesticides vary depending on the particular pesticide and the length and route of exposure. Individual pesticides have been associated with impacts to the hepatic and nervous systems.

### 2.6.4 Polychlorinated Biphenyls (PCBs)

PCBs are a group of synthetic organic chemicals that can cause a number of different harmful effects. There are no known natural sources of PCBs in the environment. PCBs typically enter the environment as mixtures containing a variety of individual chlorinated biphenyl components, known as congeners, as well as impurities. Because they don't burn easily and are good insulating materials, PCBs were used widely as coolants and lubricants in transformers, capacitors, and other electrical equipment. The manufacture of PCBs stopped in the United States in August 1977 because there was evidence that PCBs build up in the environment and may cause harmful effects. Consumer products that may contain PCBs include old fluorescent lighting fixtures, electrical devices or appliances containing PCB capacitors made before PCB use was stopped, old microscope oil, and old hydraulic oil. PCBs adhere strongly to soil and will not usually be carried deep into the soil with rainwater. They do not readily break down in soil and may persist in the soil for months or years; generally, the more chlorine atoms that the PCBs contain, the more slowly they break down. PCBs can accumulate in the leaves and above-ground parts of plants and food crops as well as in the bodies of small organisms. When these plants or organisms are prey for larger animals, PCBs may bioaccumulate in the tissue of these predators (ATSDR, 2000). The health effects from exposure to PCBs vary depending on the particular PCB and the length and route of exposure. Individual PCBs have been associated with impacts to the nervous system and reduced body weight.

### 2.6.5 Dioxins and Furans

Dioxins and furans include a family of toxic substances that share a similar structure. Most dioxins and furans are not man-made or produced intentionally but are created when other chemicals or products are made. When released into water, they are likely to attach to soil and sediment particles which may then settle to the bottom sediment of the water body. Chlorinated dioxins have the potential to accumulate in animals, resulting in measurable levels in animals higher in the food chain. Ingestion is the primary method of exposure and uptake of chlorinated dioxins to animals. Exposure in animals can lead to weight loss, liver damage, and disruption of the endocrine system. In many species of animals, chlorinated dioxins weaken the immune system and cause a decrease in the system's ability to fight bacteria and viruses. In other animal studies, exposure has caused reproductive damage and birth defects. Some animal species exposed to dioxins and furans during pregnancy had miscarriages and the offspring of animals exposed to chlorinated dioxins during pregnancy often had severe birth defects including skeletal deformities, kidney defects, and weakened immune responses. Animal studies have also shown an increased risk of cancer from exposure to CDDs (ATSDR, 1998).

### 2.6.6 Cyanide

Cyanide is a chemical group consisting of one atom of carbon connected to one atom of nitrogen by three molecular bonds (C≡N) and cyanides are compounds that contain a cyanide group. Cyanides can both occur naturally or be man-made and many are powerful and rapid-

acting poisons. Simple cyanide salts (sodium cyanide and potassium cyanide) are common examples of cyanide compounds. Certain bacteria, fungi, and algae can produce cyanide, and cyanide is found in a number of foods and plants. Many of the cyanides in soil and water come from industrial processes. The major sources of cyanides in water are discharges from some metal mining processes, organic chemical industries, iron and steel plants or manufacturers, and publicly owned wastewater treatment facilities. Other cyanide sources include vehicle exhaust, releases from certain chemical industries, burning of municipal waste, and use of cyanide-containing pesticides. Most cyanide in surface water will form hydrogen cyanide and evaporate. Cyanides are fairly mobile in soil. Once in soils, cyanide can be removed through several processes. Consequently, cyanides usually do not seep into underground water. Exposure to cyanide can affect the neurological system and result in impaired reproduction (ATSDR, 2006).

### 2.6.7 Metals

The toxicity of metals depends on the solubility and bioavailability of the particular metal. It is assumed that the water-soluble fraction in soil or sediment exhibits the greatest potential for adverse ecological risk because it is directly available for uptake by organisms.

The bioavailability and toxicity of metals in soil are influenced by soil physiochemical characteristics, including the quantity and type of organic carbon. For these reasons, the concentration of a metal in bulk soil does not represent its bioavailability or potential for toxicity (Allen and Janssen, 2006; Thakali et al., 2006a and 2006b). Rather, the bioavailable and toxic form of metals is found in the soil solution (Thakali et al., 2006a and 2006b). Metals either exist in the soil solution as free (uncomplexed) metal ions in soluble complexes with inorganic or organic ligands or associated with mobile inorganic and organic colloidal material. Common inorganic ligands are sulfate ($SO_4^{2-}$), chloride ($Cl^-$), hydroxide ($OH^-$), phosphate ($PO_4^{3-}$), nitrate ($NO_3^-$), and carbonate ($CO_3^{2-}$). Common organic ligands include low molecular weight aliphatic, aromatic, and amino acids and soluble constituents of fulvic acids.

The bioavailability and toxicity of metals in sediment and water are influenced by physiochemical characteristics, including the quantity and type of organic carbon, which affects the partitioning of constituents between soil/sediment and porewater. The freely dissolved concentrations of constituents in sediment porewater are the most direct indicator of constituent bioavailability and partitioning. Based on this principle, equilibrium partitioning theory may be used to predict the toxicity of metals in sediment based on the partitioning of simultaneously extracted metals between acid volatile sulfides, organic carbon, and porewater (USEPA, 2005a; USEPA, 2007). Because of these partitioning relationships, site-specific information regarding the factors that mitigate the bioavailability and toxicity of COIs in sediment is fundamental to the assessment of potential impacts to ecological receptors. The health effects from exposure to metals vary depending on the particular metal and the length and route of exposure. Individual metals have been associated with impacts to the urinary system, muskuloskeletal system, blood and reduced body weight.

## 2.7 Exposure Routes and Receptors Not Evaluated

This section provides the rationale for exposure routes and receptors not selected for further evaluation.

### 2.7.1 Terrestrial Plants

This ERA report indirectly evaluates and remains protective of plant communities that may inhabit the WFF. Ecological screening values (ESVs) protective of plants were used in the direct contact evaluation. For some COIs, plant-based benchmarks were less conservative than other benchmarks used during the ERA. Of the potential ecological receptors that are present at WFF, plants are not the most sensitive to the potential effects of site-related COIs (Suter et al., 2000). For example, unlike herbicides, the toxic and bioaccumulative effects of Site-related metals and explosives on plants may be mitigated by biotransformation, volatilization, and/or sequestration in root tissues.

### 2.7.2 Amphibians and Reptiles

A standardized ecotoxicological methodology has not been established, and currently, there are very few established methods to evaluate the toxicity of chemical stressors for amphibians. Also, existing ecotoxicological methods are unlikely to predict adverse ecotoxicological effects in support of the ERA (Johnson et al., 2017). Ecotoxicological data for amphibians are limited. The majority of the available ecotoxicological data on amphibians are from acute exposures in aquatic test systems (Johnson et al., 2017). Because of the conservatism in Step 1 and Step 2 of the ERA, acute ecotoxicological data will not support the assessment and measurement endpoints. Additionally, surrogate species cannot be used. Definitive comparisons with surrogate species, e.g., fish, are difficult to achieve because of variability in study design (Birge et al., 2000; Johnson et al., 2017). Despite these limitations, amphibians will be indirectly evaluated within the ERA. The proposed conservative screening approach for sediments is intended to be protective of any sensitive aquatic organism.

### 2.7.3 Water Column Community

The water column community was not explicitly evaluated within this ERA. Dissolution of COIs from resuspended sediment and groundwater discharge into surface water could expose water column organisms to unacceptable concentrations of COIs within and adjacent to the AOCs. ESVs used within this ERA to evaluate benthic macroinvertebrate exposure in surface water are indirectly protective of the water column community. For some COIs, water column organisms (daphnids) were considered during the development of chronic ESVs for surface water (Suter and Tsao, 1996).

### 2.7.4 Fish

This ERA report indirectly evaluates and remains protective of fish communities that may inhabit the estuarine environment downgradient of WFF. During ESV selection, criteria for fish were considered for sediment and water direct contact pathways (minimum of benthic macroinvertebrates and fish). The benthic macroinvertebrate community will be used as a surrogate endpoint to remain protective of direct contact and exposure. Additionally, birds and mammals will be used to evaluate the impacts of bioaccumulation and biomagnification through the food chain.

## 2.8 Receptors of Concern and Exposure Routes Selected for Evaluation

Based on the evaluation of the chemical and fate and transport characteristics of COIs across the WFF site, direct contact exposures to soil, sediment, sediment porewater, and surface water are the primary routes of exposure to ecological receptors within and near the site. Additionally, wildlife ingestion exposure pathways are also relevant due to the potential for COIs to bioaccumulate from environmental media (i.e., soil/sediment into the tissues of prey items).

Selection of potential receptors was driven by the availability of data in potentially affected habitats within and near the WFF. Given that direct contact and dietary exposure to metals are the primary exposure pathways/routes to ecological receptors, receptors of concern identified for evaluation in the ERA include the following:

- Soil macroinvertebrate community
- Benthic macroinvertebrate community
- Terrestrial wildlife
    - Mammalian invertivore: Short-tailed shrew (*Blarina brevicauda*)
    - Mammalian herbivore: Meadow vole (*microtus pennsylvanicus)*
    - Mammalian carnivore: Red fox (*Vulpes vulpes*)
    - Avian invertivore: American robin (*Turdus migratorious*)
    - Avian herbivore: Northern bobwhite (*Colinus* virginianus)
    - Avian carnivore: Red-tailed hawk (*Buteo* jamaicensis)
- Aquatic and semi-aquatic wildlife
    - Mammalian invertivore: Raccoon (*Procyon lotor*)
    - Mammalian piscivore: American mink (*Neovison vison*)
    - Avian invertivore: Marsh wren (*Cistothorus palustris*)
    - Avian piscivore: Osprey (*Pandoin halieatus*)

Summaries of exposure pathways and rationale for selected sensitive receptor groups are presented in the following sub-sections.

### 2.8.1 Soil Macroinvertebrates

Soil macroinvertebrates are the most susceptible to the effects of COIs because of their sedentary nature and direct exposure to terrestrial soil. As a result of this exposure, soil macroinvertebrates are sensitive to both acute and chronic changes in soil quality. Exposure routes for soil macroinvertebrates include:

- Direct contact/absorption of soil
- Direct/incidental ingestion of soil

Soil macroinvertebrates such as earthworms can incorporate COIs into their tissues through feeding in soil and leaf litter, in addition to burrowing in affected soils. Because earthworms and other soil macroinvertebrates are relatively immobile, these species can potentially be exposed to a maximum constituent concentration in soil during the course of their lifetime (Suter et al., 1995).

Soil macroinvertebrates penetrate and exploit the surface soil layer to varying depths, which results in varying degrees of exposure. For example, epigeic species such as arthropods can be found at the surface layer in leaf litter. Whereas epi-endogeic species such as the European earthworm (*Lumbricus rubellus*) primarily reside near or at the surface, create horizontal burrows to feed and reproduce, and are found at soil depths of approximately 8 in bgs (Sackett et al. 2012). Anecic earthworm species such as the common earthworm (*L. terrestris*) create permanent vertical burrows in soil, which contain leaf litter and soil mixed from different depths of the profile and can extend to depths of 6.5 ft bgs (Scharenbroch and Johnston, 2011). *L. terrestris* will feed on leaves on the soil surface that they drag into the burrows. However, most exposure occurs within the biologically active zone (BAZ), which operationally extends to a depth of approximately 12 in bgs (USEPA, 2015b). Within this ERA, exposure pathways to soil macroinvertebrates are considered complete and greatest within surface soil

### 2.8.2 Benthic Macroinvertebrates

Similar to soil macroinvertebrates, benthic macroinvertebrates are sensitive to both acute and chronic changes in sediment/water quality due to their sedentary nature. Exposure routes for benthic macroinvertebrates and fish include:

- Direct contact/absorption of sediment, sediment porewater, and surface water
- Direct/incidental ingestion of sediment, sediment porewater, and surface water

Benthic macroinvertebrates are generally sedentary and susceptible to adverse changes in sediment and sediment porewater quality. Additionally, USEPA (2008a) indicates that benthic and epibenthic communities (e.g., invertebrate larvae, worms, and bivalves) spend part or all of their life cycle in contact with the sediments and groundwater that comprise the GW-SW transitional zone. For benthic macroinvertebrates, exposure occurs within the BAZ, which operationally extends from the surface water interface to a depth of approximately 6 in bgs for freshwater sediment (USEPA, 2015b). Within this ERA, exposure pathways to benthic macroinvertebrates are considered complete and greatest within surficial sediment.

### 2.8.3 Birds and Mammals

Exposure routes for birds and mammals include:

- Ingestion of prey items
- Incidental ingestion of soil (terrestrial)
- Direct/incidental ingestion sediment (aquatic and semi-aquatic)
- Direct/incidental ingestion of surface water (aquatic and semi-aquatic)

A significant proportion of the biological activity occurs within the top 0-12 in for soil and 0-6 in for sediment (USEPA, 2015b); although, fossorial mammals can be encountered at depths

reaching 2 ft (USEPA, 2018). Based on likelihood of exposure and availability of surface soil and sediment data, exposure pathways to wildlife are considered complete and greatest within the 0 to 2 ft and 0 to 6 in intervals, respectively. Wildlife receptors selected for the exposure evaluation are discussed in the following subsections.

#### 2.8.3.1 Meadow Vole (Terrestrial)

Optimal meadow vole habitat consists of moist, dense grassland with substantial amounts of plant litter. In most areas, meadow voles prefer habitats with dense vegetation. However, meadow voles are the most widely distributed grazing herbivore of its size and can be found anywhere in North America with some grass cover (USEPA, 1993). The diet of the meadow vole includes grasses, sedges, seeds, flowers, leaves, roots of shrubs and small trees, bark, tubers, bulbs, and occasionally insects. Given an array of habitat types, meadow voles prefer grassy areas with an abundance of green, succulent vegetation to wooded understories (USEPA, 1993). Within the WFF, the meadow vole was included in the screening level evaluations for areas that had accessible grassy areas as opposed to mostly forests or woodlands.

#### 2.8.3.2 Short-tailed Shrew (Terrestrial)

The short-tailed shrew occupies a range of habitat types, including wetlands and uplands, and is reported to occur in both forested and open habitats (Sample and Suter, 1994). Short-tailed shrews are active on the ground surface, in leaf litter, and below the ground surface. A well-developed leaf litter layer protects shrews from moisture and temperature extremes. Earthworms are reported to be the most important food item. Millipedes, slugs, snails, and insect larvae are also important prey items. Shrew will also prey on vertebrates when other food is not available and have shown sensitivity to bioaccumulative chemicals (USEPA, 1993). Additionally, the shrew is a common prey item for owls, raptors, fox, and other carnivores (USEPA, 1993). The short-tailed shrew is expected to occupy all areas of the WFF with a complete exposure pathway to surface soil. Within this ERA, the short-tailed shrew was evaluated assuming bioaccumulation of COIs into prey items (soil macroinvertebrates) from surface soil and incidental ingestion of substrate.

#### 2.8.3.3 Red Fox (Terrestrial)

Foxes prefer a habitat mosaic over homogeneous forested stands or open areas. The red fox is characterized as an old field or edge-species since it is commonly found in areas of forests interspersed with fields, cropland and/or grasslands. The fox has a wide dietary range but is predominantly carnivorous feeding mainly on rabbits and mice (USEPA, 1993). Lesser amounts of mammals, birds, snakes, invertebrates, and plant material are consumed. The red fox is expected to occupy all areas of the WFF with a complete exposure pathway to surface soil. Within this ERA, the red fox was evaluated assuming bioaccumulation of COIs into prey items (small mammals) from surface soil and incidental ingestion of substrate.

#### 2.8.3.4 Northern Bobwhite (Terrestrial)

Bobwhites are commonly found among grassland, shrubs, and emergent vegetative areas without highly developed canopy cover. They require shaded grassy areas with low-lying cover for nesting areas (USEPA, 1993). Bobwhites forage during the daytime and eat seeds, woody

plants, grasses, and other vegetation on the ground or within inches of the soil surface. Although chicks consume mainly invertebrates, juveniles and adults are largely herbivorous. Within the WFF, the bobwhite is likely only to occur in areas where there is a combination of early succession vegetation along forested areas or scrub/shrub areas with open woodland (Central, Northern, and Southern AOCs). Due to the bobwhite's nesting and foraging habits, they require some level of ground cover as well as open feeding areas. The bobwhite will be initially evaluated using an entirely plant diet to conservatively estimate the impact of COIs in surface soil.

#### 2.8.3.5 American Robin (Terrestrial)

American robins can be found in closed canopy forests, woodlands, fields, and residential areas. During the summer, they are most commonly observed foraging in cleared areas with short-stature herbs. The diet of the American robin includes fruits and insects. The diet varies seasonally such that invertebrates dominate the diet in the spring, whereas fruits dominate in the fall/winter (USEPA, 1993). The American robin could potentially occupy all areas within the WFF and is susceptible to localized impacts in soil. Within this ERA, the American robin was initially evaluated assuming bioaccumulation of COIs into prey items (soil macroinvertebrates) from surface soil and incidental ingestion of substrate.

#### 2.8.3.6 Red-tailed Hawk (Terrestrial)

Red-tailed hawks occupy a wide variety of open to semi-open habitats including coniferous, deciduous and mixed woodlands, woodland edges, grasslands, parklands, and agricultural fields with scattered trees (USEPA, 1993). Red-tailed hawks primarily consume small mammals such as meadow voles and short-tailed shrews, but also consume birds, reptiles, and some insects. The red-tailed hawk could potentially feed in any part of the WFF. The forests surrounding the WFF provide ample locations for nesting or perching and access to a variety of habitat areas. The red-tailed hawk is expected to occupy all areas of the WFF with a complete exposure pathway to surface soil/sediment. Within this SLERA, the red-tailed hawk was evaluated assuming bioaccumulation of COIs into prey items (small mammals) from surface soil/sediment and incidental ingestion of substrate.

#### 2.8.3.7 Raccoon (Aquatic and Semi-Aquatic)

The raccoon is the ubiquitous mammalian omnivore of North America, which can be found in a wide range of habitats including urban centers. Raccoons are opportunistic and will eat a wide range of food including but not limited to seeds, fruits, grains, invertebrates, amphibians, eggs, small mammals, and human refuse (USEPA, 1993). The largest populations of raccoons are supported by areas that have both woodland and trees for climbing/nesting and shallow water for foraging. Raccoons have adapted to almost all aquatic environments including swamps, mangroves, marshes, and coastline (USEPA, 1993).

Although a true omnivore, raccoons will be conservatively evaluated assuming a 100% invertebrate diet during the SLERA – the receptor's most sensitive dietary component to WFF's COIs. The raccoon was evaluated at all AOC sites with a complete exposure pathway to sediment and/or surface water (all aquatic and semi-aquatic habitats).

#### 2.8.3.8 Mink (Aquatic and Semi-Aquatic)

Mink are the most abundant and widespread carnivorous mammal in North America (USEPA, 1993) and will occupy primarily aquatic environments such as rivers, streams, and marshes (Sample and Suter, 1994). Mink have large home ranges that are dependent on habitat type (averaging 1.85- 2.63 kilometers linearly along streams and up to 770 hectares within open habitats; USEPA, 1993). Regardless of specific habitat type, mink are rarely found more than a couple hundred meters from water (USEPA, 1993).

The mink is an opportunistic carnivore, and the composition of a mink's diet will vary depending on habitat. Within traditional aquatic systems, mink feed along shorelines consuming invertebrates, fish, and amphibians. Within semi-aquatic or terrestrial environments (such as a woodland stream), mink predominantly consume small mammals, eggs, and birds (with a preference for muskrat).

Within this SLERA, mink are evaluated as an aquatic and semi-aquatic piscivore. They were conservatively evaluated as potentially complete receptors at all AOC sites with a complete exposure pathway to sediment and/or surface water (regardless of the presence of fish). If potential adverse impacts are identified in the SLERA, habitat selection and diet will be further refined during BERA Step 3.

#### 2.8.3.9 Marsh Wren (Aquatic and Semi-Aquatic)

Marsh wren frequent saltwater and freshwater marshes that contain permanent standing water from a few centimeters to about a meter (USEPA, 1993). Marsh wrens will eat insects directly from the water surface or emergent vegetation. Breeding marsh wrens will typically only occupy marshes larger than 0.4 hectares, and average male territory can be as low as 0.006 hectares (approximately 25 x 25 ft).

Within the WFF, the marsh wren will likely only occupy areas along waterways with adjacent wetlands. The tidal marsh / wetlands adjacent to Little Mosquito Creek contains optimal habitat for marsh wrens due to available sedges and grasses for nesting and shallow water depths for feeding. Conservatively, marsh wrens will be included in the aquatic and semi-aquatic evaluation of the AOCs which have wetlands adjacent to the Little Mosquito Creek.

#### 2.8.3.10 Osprey (Aquatic and Semi-Aquatic)

In the United States, the majority of osprey populations are associated with marine environments, but large inland rivers, lakes, and reservoirs also may support osprey (Henny, 1986 and 1988). Good nesting sites in proximity to open, shallow water and a plentiful supply of fish are the primary resources required for osprey success (Poole, 1989). The tops of isolated and often dead trees and man-made structures are preferred nesting sites. Osprey often nest in colonies (Poole, 1989). Osprey are almost completely piscivorous, although they have been observed on occasion taking other prey including birds, frogs, and crustaceans (Brown and Amadon, 1968). Their prey preferences change seasonally with the abundance of the local fish (Edwards, 1988; Greene et al., 1983).

Within the WFF, the osprey will likely occupy areas along the Little Mosquito River adjacent to the Northern, Central, and Southern AOC sites. Within this SLERA, the osprey was evaluated

assuming bioaccumulation of COIs into prey items (fish) from sediment and incidental ingestion of substrate/water.

## 2.9 Assessment and Measurement Endpoints

An assessment endpoint is an explicit expression of the environmental value that is to be protected. Because of the nature of potential contaminants and the receptors of concern (macroinvertebrates, birds, and mammals), general assessment endpoints of maintenance of the upland, terrestrial community (WFF) and nearby aquatic and semi-aquatic communities (Little Mosquito Creek and wetlands) composition are selected.

Measurement endpoints are the measurable ecological characteristics that are related to the assessment endpoints. Measurement endpoints were selected based on their direct relationship to the maintenance of the respective receptor populations. Hence, potential adverse effects on survival, reproduction, and growth are selected as the measurement endpoints. The assessment endpoint(s) and their associated measurement endpoint for the representative receptors are shown below in **Table 2-3**.

## 2.10 Ecological Screening Benchmarks

The maximum concentrations of COIs from each exposure area were compared to their respective chronic ESVs to identify COPECs for each sample medium. The screening-level effects evaluation establishes constituent exposure concentrations that represent thresholds for adverse effects. Benchmarks representing no observed effects concentrations (NOECs) were used preferentially during Step 2. Screening levels used within this ERA are presented in **Attachment A**. The hierarchy used to identify conservative screening benchmarks established for the selection of COPECs in each medium is presented below.

- Direct Contact
    - Surface soil ESVs were selected as the minimum of either terrestrial plant or soil macroinvertebrate benchmarks. The following hierarchy of sources was used to identify terrestrial, direct contact ESVs.
        - USEPA (2008b). Ecological Soil Screening Levels (USEPA Eco-SSLs).
        - USEPA (2018). USEPA Region 4 ESVs.
        - USEPA (2003). USEPA Region 5 Ecological Screening Levels (ESLs).
        - LANL (2017). Los Alamos National Laboratory (LANL) NOEC ESLs.
    - Sediment and surface water/pore water ESVs were selected as the minimum freshwater or saltwater value for benthic macroinvertebrates, fish, or general aquatic community organisms. The following hierarchy of sources was used to identify aquatic and semi-aquatic, direct contact ESVs.
        - USEPA (2006). Region 3 Biological Technical Assistance Group (BTAG) Screening Values.
        - USEPA (2018). USEPA Region 4 ESVs.
        - USEPA (2003). USEPA Region 5 ESLs.

        - LANL (2017). LANL NOEC ESLs.
    - If no direct contact ESV was available from the sources above, soil and sediment ESVs were modeled for non-ionic, organic compounds using the adapted biotic ligand models from USEPA (2018).
    - If no direct contact ESV was available from the sources above, surface water/pore water ESVs were selected as the minimum chronic value derived by the USEPA's ECOSAR Predictive Model (USEPA, 2017).
- Wildlife
    - For terrestrial receptors, USEPA (2008b), USEPA (2018), USEPA (2003), and LANL (2017) were used to select soil ESVs specific to birds and mammals. These ESVs were used in conjunction with the direct contact values identified above. An exceedance of a wildlife-based ESV was used to determine COIs for food chain-based, dose rate models (DRMs).
    - For aquatic receptors, USEPA (2006) and LANL (2017) were used to select sediment and water ESVs specific to birds and mammals. If no wildlife-based ESVs were available, the direct contact ESV was retained if the COI was identified as an important, bioaccumulative compound within USEPA (2000).

# 3. Step 2: Screening Level Exposure Estimate and Risk Calculation

This section describes the methodology used to conduct screening-level exposure estimates and risk calculations for selected receptor categories, consistent with Step 2 of ERAGS (USEPA, 1997). This phase of the ERA uses the results of the screening-level problem formulation and ecological effects evaluation in Step 1 to estimate exposure and characterize risk. This section:

- Identifies exposure areas
- Describes the data used to characterize ecological exposure
- Presents the screening level exposure estimates
- Describes the screening level calculation and risk characterization process
- Specifies the criteria for COPEC selection and
- Presents the SMDP

## 3.1 Exposure Areas

An exposure area consists of a location within which an exposed ecological receptor can reasonably be assumed to move about and where contact with an environmental medium is equally possible at all points within the exposure area. For terrestrial exposure, all soil AOCs were each treated as separate exposure areas since the range of some ecological receptors are well within the size of each AOC. For aquatic and semi-aquatic exposure, the downgradient estuarine habitat was separated from the upgradient sediment samples located within a drainage channel (referred to as “Downgradient Estuarine” and “Upgradient Drainage” within this ERA, respectively). **Figure 2-1** identifies the exposure areas considered in the ERA.

## 3.2 Data Used to Characterize Ecological Exposure

The following data was used within each exposure area to estimate potential for adverse impacts to ecological receptors:

- Northern AOC
    - Four (4) surface soil samples
- Western AOC
    - Four (4) surface soil samples
- Central AOC
    - Nine (9) surface soil samples
- Southern AOC
    - Fourteen (14) surface soil samples
- Upgradient Drainage

    - Two (2) sediment samples
- Downgradient Estuarine
    - Nineteen (19) sediment samples
    - Seven (7) surface water samples
    - Eleven (11) pore water samples

For three groups of COIs (PAHs, DDD/DDE/DDT, and dioxins/furans), summations were used to evaluate ecological exposure in various media. These summations include total high and low molecular weight PAHs (soil), total PAHs (sediment, surface water, pore water), total DDD/DDE/DDT (all media), and total dioxins/furans using a relative toxicity equivalence quotient (TEQ) for birds, fish, and mammals (USEPA, 2008c). The Kaplan Meier method was used when non-detect data were present per USEPA (2016b) guidance.

## 3.3 Screening Level Exposure Estimate and Methodology

The preliminary exposure estimate presents the most conservative exposure scenario based on the most conservative exposure assumptions. Maximum concentrations were used to evaluate exposure. This approach addresses wildlife with small home ranges and sedentary organisms, e.g., soil or benthic macroinvertebrates.

- Direct Contact Evaluation
    - For terrestrial exposure, maximum COI concentrations in surface soil were compared to conservative ESVs known to be protective of soil macroinvertebrates and plants.
    - For aquatic and semi-aquatic exposure, maximum COI concentrations in sediment, surface water, and pore water were compared to conservative ESVs known to be protective of benthic macroinvertebrates, fish, and general aquatic community organisms.
    - COIs which were completely non-detect were screened using their maximum limits of quantitation (LOQs). COPECs based on LOQs will be reviewed during BERA Step 3a.
- Preliminary Wildlife Screening
    - For both avian and mammalian terrestrial receptors, maximum detected COI concentrations in surface soil were compared to ESVs protective of wildlife. Exceedances of ESVs protective of wildlife require additional DRMs to estimate the potential risk for each wildlife receptor.
    - For both avian and mammalian aquatic/semi-aquatic receptors, maximum detected COI concentrations in sediment and surface water were compared to ESVs protective of wildlife. Exceedances of ESVs protective of wildlife require additional DRMs to estimate the potential risk for each wildlife receptor.
    - COIs which were completely non-detect were not screened against wildlife-based ESVs or retained for DRMs. Uncertainties related to modeling of non-

detect data above wildlife ESVs will be discussed within **Section 5 Uncertainty Analysis**.

- Dose Rate Modeling
    - A DRM was used to generate a total estimated daily dose ($EDD_{total}$) of each COI experienced by each selected receptor. $EDD_{total}$ was compared against a TRV to assess the potential for ecological risk. $EDD_{total}$ consists of the sum of doses obtained from diet ($EDD_{diet}$) and the incidental ingestion of the substrate, i.e., soil or sediment ($EDD_{substrate}$). The contribution of surface water was considered negligible only for terrestrial receptors with prey items consisting of each receptors' primary source of dietary water.
    - Dietary composition for wildlife receptors was assumed to consist of 100% of the most contaminated prey item. Wildlife DRMs based on maximum detected COI concentrations assumed an area use factor (AUF) of 100%; this represents the worst-case exposure scenario for wildlife and assumes that receptors continuously forage at the maximum detected COI concentration.
    - $EDD_{total}$ for each constituent was compared to conservative TRVs for that constituent. TRVs constitute threshold effects concentrations derived from published toxicity test data. Two TRVs were used including the NOAEL and the Lowest Observed Adverse Effect Level (LOAEL). The NOAEL and LOAEL are daily dose levels normalized to the body weight of the test animals, e.g., milligrams of chemical per kilogram of body weight per day (mg/kg, bw-day).
        - Within a single study and endpoint (e.g., growth or reproduction), the NOAEL represents the highest tested concentration that did not result in the adverse effect, and the LOAEL represents the lowest tested concentration that did result in the adverse effect. Of these TRVs, the NOAEL is the conservative estimate of a safe exposure level, and the LOAEL is a more realistic estimate of exposures that may pose a risk to the receptor.
    - Additional details of DRMs and wildlife TRVs used in the ERA are presented in **Attachment B**.

## 3.4 Screening Level Risk Calculations and Risk Characterization

Potential risks associated with the ecological exposure estimates are expressed as a hazard quotient (HQ), which represents the ratio of the exposure point concentration (EPC) to the ESV for direct contact pathways or the calculated EDD to the TRV for wildlife ingestion pathways. As previously stated, the maximum detection or LOQ (for non-detected COIs) was used as the EPC during Step 2.

Based on the magnitude of the HQs, potential risks may be interpreted as follows:

- A HQ less than 1 based on a NOEC or NOAEL indicates that potential risk is not expected because the estimated exposure has not been demonstrated to cause adverse ecological effects (USEPA, 1997) and

- A HQ greater than or equal to 1 based on a NOEC or NOAEL indicates some potential for risk and further refinements should be made to reduce uncertainty.

This decision criterion reflects the abundance of caution adopted for the ERA evaluation. LOAEL-based TRVs are provided in **Attachment B** for reference in SLERA Step 2 but are not used for interpreting risk characterization results until BERA Step 3a.

The preliminary exposure estimate results for all receptors are summarized below. **Table 3-1** and **Table 3-2** present the direct contact evaluation and preliminary wildlife screening of surface soil and sediment/surface water/pore water, respectively. **Table 3-3** summarizes the DRM results for surface soil and sediment/surface water COIs exceeding wildlife screening values for all relevant receptors. Full DRM results, explanation of model parameters, and wildlife TRVs can be found in **Attachment B.**

Based on the evaluation of COI concentrations in relevant media, the following COPECs were identified at WFF (*italics indicate COPEC was 100% non-detect*):

- Northern AOC
    - Direct Contact (soil): chromium, thallium, *selenium*
    - Wildlife (soil): bis(2-ethylhexyl)phthalate, vanadium
- Western AOC
    - Direct Contact (soil): chromium, mercury, thallium, *selenium*
    - Wildlife (soil): bis(2-ethylhexyl)phthalate, vanadium
- Central AOC
    - Direct Contact (soil): benzaldehyde, Total HMW PAHs, chromium, cobalt, lead, manganese, mercury, nickel, selenium, thallium, zinc, *atrazine*
    - Wildlife (soil): bis(2-ethylhexyl)phthalate, Total HMW PAHs, Total DDD/DDE/DDT, chromium, lead, nickel, selenium, vanadium, zinc
- Southern AOC
    - Direct Contact (soil): alpha-chlordane, gamma-chlordane, barium, chromium, cobalt, copper, lead, manganese, mercury, nickel, selenium, thallium, zinc, *atrazine*
    - Wildlife (soil): bis(2-ethylhexyl)phthalate, Total DDD/DDE/DDT, Total TEQ (bird), Total TEQ (mammal), antimony, cadmium, chromium, copper, lead, nickel, selenium, silver, vanadium, zinc
- Qualitative evaluation of aluminum and iron in soil
    - Per USEPA (2008b) guidance, the potential adverse ecological effects for aluminum and iron are directly related to bioavailability and indirectly evaluated through pH levels in soil. Aluminum is only considered a soil COPEC when pH is less than 5.5 and iron is only considered a COPEC when pH is outside 5-8 and soil contains flocculent that may enhance potential toxicity of other metals (USEPA, 2008b).

  - As presented in **Section 2.1.1**, Molena loamy sand is the predominant soil type found with each soil AOC (>98%). Laboratory measurements using the 1:1 water method suggest a pH rating of 5.5 – as obtained from NRCS (2020).
  - Aluminum and iron will not be retained as COPECs for any soil AOC at WFF.

- Upgradient Drainage
  - Direct Contact (sediment): carbon disulfide, Total DDD/DDE/DDT, antimony, arsenic, barium, cadmium, copper, iron, lead, mercury, nickel, silver, zinc, *toxaphene, cyanide*
  - Wildlife (sediment): Total DDD/DDE/DDT, lead, vanadium
- Downgradient Estuarine
  - Direct Contact (sediment): acetone, carbon disulfide, bis(2-ehylhexyl)phthalate, di-n-octyl phthalate, Total TEQ (fish), aluminum, arsenic, barium, chromium, copper, iron, lead, nickel, selenium, *4-chloroaniline, toxaphene, cyanide, antimony*
  - Direct Contact (surface water): aluminum, arsenic, barium, calcium, chromium, copper, iron, lead, magnesium, mercury, potassium, selenium, *1,1,2-trichlorotrifluoroethane, 1,2-dibromo-3-chloropropane, 1,2-dibromoethane, chloroethane, chloromethane, cis-1,3-dichloropropane, dichlorodifluoromethane, methyl acetate, trans-1,3-dichloropropene, trichlorofluoromethane, 2-chloronaphthalene, 4,6-dinitro-o-cresol, 4-bromophenyl phenyl ether, 4-chloro-3-methyl phenol, 4-chlorophenyl phenyl ether, acetophenone, bis(2-chloroethoxy)methane, bis(2-chloroethyl)ether, bis(2-chloroisopropyl)ether, caprolactam, hexachlorobenzene, hexachlorocyclopentadiene, n-nitroso-di-n-propylamine, pentachlorophenol, alpha-chlordane, heptachlor, toxaphene, Aroclor 1016, Aroclor 1221, Aroclor 1232, Aroclor 1242, Aroclor 1248, Aroclor 1254, Aroclor 1260, cyanide, cadmium, silver, thallium*
  - Direct Contact (pore water): arsenic, barium, cadmium, calcium, chromium, magnesium, manganese, mercury, potassium, sodium, *1,1,2-trichlorotrifluoroethane, 1,2-dibromo-3-chloropropane, 1,2-dibromoethane, 1,2-dichlorobenzene, chloroethane, chloromethane, cis-1,3-dichloropropane, dichlorodifluoromethane, hexachlorobutadiene, methyl acetate, trans-1,3-dichloropropene, trichlorofluoromethane, 2-chloronaphthalene, 4,6-dinitro-o-cresol, 4-bromophenyl phenyl ether, 4-chlorophenyl phenyl ether, acetophenone, bis(2-chloroethoxy)methane, bis(2-chloroethyl)ether, bis(2-chloroisopropyl)ether, caprolactam, di-n-butyl phthalate, hexachlorobenzene, hexachlorocyclopentadiene, n-nitroso-di-n-propylamine, pentachlorophenol, aluminum, antimony, cobalt, copper, lead, selenium, silver, thallium*
  - Wildlife (sediment and surface water): bis(2-ehylhexyl)phthalate, Total TEQ (bird), Total TEQ (mammal), aluminum, chromium, selenium, vanadium

## 3.5 Scientific Management Decision Point

The SMDP is a determination made at the culmination of the ERA process that states whether there is sufficient information to make a decision regarding risk management strategies (USEPA, 1997). The SMDP rendered at the end of the preliminary risk calculation does not set a clean-up goal. As stated in USEPA (1997), one of the following conclusions is reached after Step 2:

- There is adequate information to conclude that ecological risks are negligible and therefore no need for remediation on the basis of ecological risk;
- The information is not adequate to a make a decision at this point and the ecological risk assessment will continue to Step 3; or
- The information indicates a potential for adverse ecological effects, and a more thorough assessment is warranted.

Based on the results of the direct contact evaluation and wildlife DRMs, the following SMDPs have been reached:

- The information is not adequate to a make a decision at this point and the ecological risk assessment continued to Step 3.
    - All Soil AOCs
        - Surface Soil – results of the direct contact evaluation and wildlife DRMs have indicated potential adverse effects for soil macroinvertebrates and wildlife.
    - Upgradient Drainage
        - Sediment – results of the direct contact evaluation and wildlife DRMs have indicated potential adverse effects for benthic macroinvertebrates and wildlife.
    - Downgradient Estuarine
        - Sediment/Surface Water/Pore Water – results of the direct contact evaluation and wildlife DRMs have indicated potential adverse effects for benthic macroinvertebrates and wildlife.

# 4. Step 3a: Constituents of Potential Ecological Concern Refinement

SLERA Steps 1 and 2 were used to select COPECs and evaluate ecological risk under a conservative, “worst-case” scenario. SLERA Steps 1 and 2 were also used to identify which constituents can be eliminated from further consideration and those that should be evaluated further. Because of the conservative assumptions used during SLERA Steps 1 and 2, some of the COPECs retained for BERA Step 3a COPEC refinement might pose negligible risk.

Step 3a represents a sub-tier of Step 3 within ERAGS and is designed to refine the list of COPECs by considering additional factors. By conducting a refined exposure evaluation, Step 3a can reduce the list of COPECs and determine if there are COPECs that truly warrant further evaluation with a BERA and/or remediation. Furthermore, Step 3a can focus on the potential risk drivers and exposure areas where the likelihood of adverse ecological effects is greatest.

## 4.1 Step 3a COPEC Refinement Approach

The BERA Step 3a refinements discussed within these subsections below include:

- Elimination of COPECs based on detection frequency and spatial distribution;
- Calculation and selection of refined EPCs;
- Refined direct contact evaluation for soil and benthic macroinvertebrates; and
- Refinement of DRMs for birds and mammals.

**Table 4-1** summarizes the detected COPECs carried forward into Step 3a for each medium and exposure area (see **Section 4.1.1** for COPECs based on LOQs).

### 4.1.1 Frequency, Magnitude, and Spatial Distribution of Detected Chemicals

COPECs identified in SLERA Step 2 were considered for exclusion from the BERA Step 3a evaluation if the following criteria were met:

- The COPEC was detected infrequently in one or two media types (less than 5% of samples) and
- The COPEC was not detected in any other sample medium.

Due to the varied history of each exposure area, multiple lines of evidence will be considered for each COPEC in consideration for exclusion. Any deviation from the above points will be discussed briefly below and considered in the uncertainty analysis for this evaluation. **Table 4-2** summarizes the COPECs removed from the Step 3a refined evaluation (the full RI/SFI data set is included within AECOM [2022]).

### 4.1.2 Refinement of Exposure Point Concentrations

The upper confidence limit (UCL) of the mean was used as a refined EPC for COPECs with at least eight (8) samples and two (2) distinct detects. The UCLs were calculated with ProUCL 5.1 (USEPA, 2016b). The ProUCL 5.1 output reports are included within **Attachment C**.

### 4.1.3 Refined Direct Contact Evaluations

The refined EPCs of direct contact COPECs, not excluded in **Table 4-2**, were compared to their respective refined ESVs to identify Step 3a COPECs. Selected refined ESVs and the refined direct contact evaluations are presented in **Attachment D**. The hierarchy used to identify refined screening benchmarks is presented below for each medium.

- Surface soil
    - USEPA (2008b) Eco-SSLs reported for soil macroinvertebrates
        - The geometric mean of eligible toxicity values protective of growth and reproduction; in cases where a geometric mean could not be calculated, the minimum eligible toxicity value was used as a refined ESV.
    - USEPA (2018) Region 4 ESVs reported for soil macroinvertebrates
        - If this value was based on a NOEC value, the LOEC value from LANL (2017) was used instead if applicable.
    - LANL (2017) LOEC soil ESLs protective of soil macroinvertebrates
    - If no soil macroinvertebrate ESVs were available, terrestrial plant ESVs were selected if applicable.
- Sediment
    - USEPA (2018) Region 4 Refined ESVs reported for sediment
    - LANL (2017) LOEC sediment ESLs protective of aquatic community organisms
- Surface water and pore water
    - USEPA (2018) Region 4 Refined ESVs reported for surface water
    - LANL (2017) LOEC water ESLs protective of aquatic community organisms

### 4.1.4 Refined Wildlife Dose Rate Models

Within SLERA Step 2, an abundance of caution was used when modeling food chain exposure via wildlife DRMs. Refined Step 3a receptor profiles, bioaccumulation models, and wildlife DRMs are provided in **Attachment E**. NOAEL and LOAEL TRVs presented in **Attachment B** with the Step 2 DRMs are still applicable for the refined Step 3a DRMs.

The following elements of the wildlife DRMs were refined to provide more representative estimates of potential hazard to avian and mammalian receptors:

- Refined EPC
    - The UCL of the mean was used as a refined EPC for COPECs with at least eight (8) samples and two (2) distinct detects. The UCLs were calculated with ProUCL 5.1 (USEPA, 2016b). Tables summarizing statistics and refined EPC selection for each site/medium and the ProUCL output reports are included with **Attachment C**.
- Refined dietary composition

    - Dietary components were adjusted to reflect representative dietary components (if applicable). These adjustments were made based on mean composition provided in either USEPA (1993) or Sample and Suter (1994).

- LOAEL-based TRVs
    - During the selection of wildlife TRVs within the SLERA, preference was given to the most conservative NOAEL TRV. NOAEL-based TRVs were used to protect wildlife species at the individual level. This may be appropriate to protect T&E species where the loss of one individual may have an adverse effect on the survival of the population. However, the conservative use of NOAEL-based TRVs may overestimate risk to populations of non-endangered species.
    - For BERA Step 3a, refinements were made to include a LOAEL TRV based on representative effects, primarily growth and reproduction. LOAEL TRVs represent the lowest observed concentration at which measurable effects within an endpoint (i.e., growth or reproduction) would be expected for an individual receptor. LOAEL–based TRVs were used in Step 3a, in conjunction with the NOAEL-based TRVs, to establish a range of risk for ecological resources for consideration by risk managers in making risk management decisions.

## 4.2 Refined Risk Calculations and Risk Characterization

The refined exposure estimates represent a more realistic exposure scenario based on the comparisons of refined EPCs to refined direct contact ESVs, DRM assumptions, and TRVs. A refined characterization of potential risks is presented in the sections below based on these exposure assumptions to focus the list of COPECs and exposure pathways that may warrant further evaluation. Summaries of the refined direct contact evaluations (**Table 4-3 and Table 4-4**) and refined DRMs (**Table 4-5**) are provided below.

Based on the evaluation of refined COPEC concentrations in relevant media, the following refined COPECs (i.e., refined or LOAEL HQ > 1) were identified at WFF (*italics indicate COPEC was 100% non-detect*):

- Northern AOC
    - Direct Contact (soil): no refined COPECs retained during Step 3a
    - Wildlife (soil): no refined COPECs retained during Step 3a
- Western AOC
    - Direct Contact (soil): no refined COPECs retained during Step 3a
    - Wildlife (soil): no refined COPECs retained during Step 3a
- Central AOC
    - Direct Contact (soil): nickel
    - Wildlife (soil): nickel

- Southern AOC
    - Direct Contact (soil): barium, chromium, copper, manganese, mercury, zinc
    - Wildlife (soil): Total DDD/DDE/DDT, Total TEQ (Mammal)
- Upgradient Drainage
    - Direct Contact (sediment): Total DDD/DDE/DDT
    - Wildlife (sediment): no refined COPECs retained during Step 3a
- Downgradient Estuarine
    - Direct Contact (sediment): bis(2-ethylhexyl)phthalate, di-n-octyl phthalate, Total TEQ (Fish)
    - Direct Contact (surface water): *silver*
    - Direct Contact (pore water): sodium, *aluminum, antimony, cobalt, copper, lead, selenium, silver, thallium*
    - Wildlife (sediment and surface water): bis(2-ethylhexyl)phthalate, aluminum

## 4.3 Step 3a COPEC Refinement Summary

Based on the results of the refined direct contact evaluation and refined wildlife DRMs, the following BERA Step 3a conclusions have been reached:

- Northern AOC
    - No refined COPECs were retained within the refined direct contact evaluation and wildlife DRMs (all LOEC/LOAEL HQs < 1).
- Western AOC
    - No refined COPECs were retained within the refined direct contact evaluation and wildlife DRMs (all LOEC/LOAEL HQs < 1).
- Central AOC
    - The refined wildlife DRMs indicated that nickel should be retained as a refined COPEC due to LOAEL HQs = 2 and 8 for the American robin and short-tailed shrew, respectively. Nickel was the only COPEC with a refined HQ > 1 within the refined direct contact evaluation (HQ = 2).
- Southern AOC
    - Multiple metals (barium, chromium, copper, manganese, mercury, and zinc) identified during refined direct contact evaluation with refined HQs > 1. Additionally, Total DDD/DDE/DDT and Total TEQ (Mammal) had refined LOAEL HQs > 1 for the red-tailed hawk and short-tailed shrew respectively.
- Upgradient Drainage
    - Of the limited sediment samples (n = 2), only Total DDD/DDE/DDT had a refined HQ > 1. Total DDD/DDE/DDT is non-detect in downgradient sample

locations. Adverse effects of sediment transport to the downgradient environment via the upgradient drainage channel is unlikely (soil AOCs are most likely source).

- These detections in the upgradient area may be related to historical maintenance activities where spraying of pesticides would have occurred along perimeter of cleared areas to control growth.

- Downgradient Estuarine
  - Due to elevated LOQs and no information on sample dilution, several metals have elevated refined HQs within the refined direct contact evaluation for pore water. However, concentrations of these metals within surface water indicate that refined HQs do not exceed 1 for any detected metal. The only detected COPEC with a refined HQ > 1 is sodium (HQ = 2). The adverse impacts of elevated sodium within an estuarine – marine environment are expected to be negligible, if present at all, for direct contact exposure.
  - Both the refined direct contact evaluation and wildlife DRMs have indicated potential impacts to sediment that may adversely impact aquatic/semi-aquatic ecological receptors. Refined and LOAEL HQs for bis(2-ethylhexyl)phthalate were 48 and 11/40 (osprey/marsh wren), respectively. Di-n-octyl phthalate and Total TEQ (Fish) had elevated refined HQs above 1. Within the refined wildlife DRMs, aluminum had LOAEL HQs from 5 to 51; however, there is considerable uncertainty on the accuracy of the estimated prey concentrations (no available models, so tissue concentrations were assumed equal to sediment).
  - Although no breeding populations have been noted, the downgradient estuarine marsh and wetlands could provide potential habitat for the eastern black rail (Virginia state endangered species). Detections of the eastern black rail have been restricted to bayside, Accomack County – thus, suggesting that there is a potential for occurrence and LOAEL TRVs may not be protective enough.

The results of the Step 3a COPEC Refinement (presented above) will be used with the Uncertainty Analysis (see **Section 5**) to reach a final SMDP. The final SMDP and further recommendations (if applicable) will be presented in **Section 6**.

# 5. Uncertainty Analysis

An uncertainty analysis was performed to identify assumptions and procedures that may result in uncertainty in the estimation of exposure or the characterization of risk. Uncertainty in the ERA is assessed with respect to the following:

- Effects and exposure assessment and
- Risk characterization.

Assumptions and other factors that tend to overestimate, underestimate, or have an unknown effect on the findings of the primary phases of the ERA are presented and discussed in the following sections.

## 5.1 Exposure and Effects Assessment

Sources of uncertainty associated with the effects and exposure assessment made in the ERA are listed below:

- Duplicate data
    - Magnitude – minimal (under/overestimate)
    - Rationale – during this evaluation, duplicate samples were kept as independent samples. Duplicate samples were not biased and collected randomly during both the RI and SFI. Any effects from retaining duplicates were expected to be minimal given the random approach for selecting duplicate locations (equal chance to under or overestimate risk). Duplicates were retained during Step 3a refinements to provide higher sample populations for sites and media with less data. Effect on UCL calculations would be negligible for larger sample populations.
- COI bioavailability
    - Magnitude – minimal (overestimate)
    - Rationale – chemical analyses measured the total levels of the constituents rather than the bioavailable toxic forms. By using total concentrations, this assessment assumes that the entire fraction is bioavailable and toxic. This is likely a very conservative assumption that varies in magnitude from constituent to constituent. It is also likely that, to some degree, constituents adsorb to fine-grained particles and/or complex with organic ligands. Such actions may change the chemical speciation of the constituent to a less toxic form or reduce the concentrations of bioavailable chemicals. Hence, the use of the total concentrations to estimate exposure does not take into account these changes in speciation or reductions in toxicity and, therefore, likely overestimates risk when compared to toxicological benchmarks derived from more bioavailable and toxic forms.
- Selection of ESVs
    - Magnitude – minimal (overestimate)

    - Rationale – ESVs presented in SLERA Step 2 are selected to identify conditions that are not expected to lead to adverse ecological harm so that COIs can be eliminated from further evaluation due to a lack of potential risks. Therefore, the screening benchmarks are highly conservative (to avoid eliminating a COI that may cause a risk), do not reflect Site-specific conditions, and cannot account for potentially antagonistic or synergistic effects between different compounds. Refinements made during BERA Step 3a were used to minimize uncertainty generated during SLERA Step 2 screening by using LOEC- and LOAEL-based benchmarks when available.

- Qualitative evaluation of aluminum and iron in soil
    - Magnitude – unknown (underestimate)
    - Rationale – per USEPA (2008b) guidance, the potential adverse ecological effects for aluminum and iron are directly related to bioavailability and indirectly evaluated through pH levels in soil. Ultimately, ecological risk for these constituents in soil is not quantifiable using the HQ method outlined in USEPA (1997). The impact of excluding aluminum and iron as COPECs is expected to be minimal.

## 5.2 Risk Characterization

Sources of uncertainty associated with the risk characterization made in the ERA are listed below:

- Synergistic and antagonistic effects
    - Magnitude – minimal (under/overestimate)
    - Rationale – exposures to ecological receptors involve more than one type of contaminant. This raises the possibility that synergistic or antagonistic interactions might occur. However, data are generally not adequate to permit any quantitative adjustment in toxicity values or risk calculations based on interactions between different compounds. If any of the COPECs act by a similar mode of action, total risks could have been higher than estimated. Conversely, if the COPECs act antagonistically, total risks could have been lower than estimated.
- Application of hazard quotients
    - Magnitude – minimal (overestimate)
    - Rationale – the application of hazard quotients to quantify potential ecological risk has certain limitations although the USEPA recommends this approach for the screening-level risk calculation. One of the advantages is that the procedure intentionally overestimates risks to “ensure that potential ecological threats are not overlooked” (USEPA, 1997). However, the HQ method does limit the information obtained because it provides only a single point of comparison for the exposure-response relationship.
- Single-species endpoints

    - Magnitude – unknown (under/overestimate)
    - Rationale – single-species, single-contaminant laboratory studies are used to estimate ecological effects at the population level. The risk assessment used toxicological data that were collected on an individual basis, not on a population level. Therefore, the HQs represent potential risk to a single individual organism, not to a population or community. This potential risk is extrapolated to include the entire population as a whole.

- Incomplete characterization
    - Magnitude – minimal (under/overestimate)
    - Rationale – given the use of conservative assumptions regarding exposure and potential toxicological effects, there is minimal uncertainty that the potential ecological risks towards ecological receptors from Site-related constituents went undetected in the ERA process.

## 5.3 Summary of Uncertainty

In general, conservative estimates or assumptions were made for most parameters associated with ecological exposures and effects in SLERA Steps 1 and 2. More realistic refinements were made during BERA Step 3a COPEC refinement to reduce uncertainties in the final conclusions. Therefore, confidence is high that the conclusions regarding the potential for adverse ecological harm are adequately conservative to quantify potential risks to soil macroinvertebrates, benthic macroinvertebrates, birds, and mammals.

Page Intentionally Left Blank

# 6. Conclusions and SMDP Recommendation

The overall objective of this ERA was to determine whether potentially adverse ecological effects are occurring, or may occur, due to Site-related constituents in relevant media. Potential for risks were evaluated by screening in a SLERA framework that identified a limited number of COPECs. The evaluations for these COPECs were further refined in the context of BERA Step 3a of the ERAGS.

The results of the SLERA, BERA Step 3a COPEC refinement, and the consideration of the uncertainties present in the evaluation support the following conclusions:

- “There is adequate information to conclude that ecological risks are negligible and therefore no need for remediation on the basis of ecological risk” (USEPA, 1997)
    - Northern AOC: soil macroinvertebrates and terrestrial wildlife
    - Western AOC: soil macroinvertebrates and terrestrial wildlife
    - Upgradient Drainage: benthic macroinvertebrates and aquatic/semi-aquatic wildlife
- The information indicates a potential for adverse ecological effects
    - Central AOC: soil macroinvertebrates and terrestrial wildlife
    - Southern AOC: soil macroinvertebrates and terrestrial wildlife
    - Downgradient Estuarine: benthic macroinvertebrates and aquatic/semi-aquatic wildlife
        - Impacts to sediment greatest within exposure area – adverse population-level effects to ecological receptors via surface water and pore water are unlikely.

## Table 2-1. Summary of Soil Types

| Soil Type | Percent of Area of Concern (AOC) | Description |
|---|---|---|
| **Northern AOC** | | |
| MoD | 97.8 | Molena loamy sand, 6 to 35 percent slopes – well drained to excessively drained sands or gravelly sands with a high rate of water transmission. Laboratory measurement pH rating of 5.5 using the 1:1 water method. (NRCS 2020). |
| BoA | 2.4 | Bojac fine sandy loam, 0 to 2 percent slopes – similar to above but with lower permeability and lower percentage of coarser sand. Laboratory measurement pH rating of 5.1 using the 1:1 water method. |
| **Central AOC** | | |
| MoD | 100 | See initial description above |
| **Southern AOC** | | |
| MoD | 100 | See initial description above |
| **Western AOC** | | |
| MoD | 100 | See initial description above |
| **Surrounding Wetland Area** | | |
| MaA | 95.0 | Magotgha fine sandy loam, 0 to 2 percent slopes – frequently flooded but not ponded and typically found in salt marshes on coastal plains. Poorly drained with water movement in the most restricted layer being moderately high. |
| ChA | 5.0 | Chincoteague silt loam, 0 to 1 percent slopes – similar to above but very frequently flooded. |

## Table 2-2. Review of Threatened and Endangered Wildlife Species

| Common Name | Scientific Name | Status | Potential to Occur at Main Base WFF? | Rationale |
|---|---|---|---|---|
| **Birds** | | | | |
| Piping Plover | *Charadrius melodus* | T | Unlikely | Nesting and breeding territory typically occur on sandy upper beaches where scattered grass tufts are present. Home range and foraging area during the breeding season generally is confined to the vicinity of the nest. |
| Wilson's Plover | *Charadrius wilsonia* | SE | Unlikely | Nests principally on sand or bare soil near salt or brackish water. In Virginia, nests on the upper portions of sandy beaches on barrier islands, usually within 30 meters of dune vegetation but not in dense vegetation. |
| Peregrine Falcon | *Falco peregrinus* | ST | Unlikely | Requires cliffs for nesting locations. When not breeding, occurs in areas including farmlands, marshes, lakeshores, river mouths, tidal flats, dunes and beaches, broad river valleys, cities, and airports. |
| Gull-billed Tern | *Gelochelidon nilotica* | ST | Unlikely | Nesting sites confined to sandy barrier islands, beaches, sandy shores of saline lagoons and marshes, and artificially produced dredge spoil islands. |
| Black Rail | *Laterallus jamaicensis* | SE | **Yes** | Breeding areas include salt, brackish, and freshwater marshes, pond borders, wet meadows, and grassy "swamps". Detections within Maryland and Virginia only noted to bayside locations within Accomack County. |
| **Reptiles and Amphibians** | | | | |
| Loggerhead (Sea Turtle) | *Caretta caretta* | T | Unlikely | In Chesapeake Bay, occurs mainly in deeper channels, usually at river mouths or in the open bay. |
| **Invertebrates** | | | | |
| Northeastern Beach Tiger Beetle | *Cicindela dorsalis dorsalis* | T | Unlikely | All subspecies occur on seashores, including beaches of lower Chesapeake Bay. Requires sandy beaches and dunes for burrowing. |
| **Flora** | | | | |

| Common Name | Scientific Name | Status | Potential to Occur at Main Base WFF? | Rationale |
|---|---|---|---|---|
| Sea-beach amaranth | *Amaranthus pumilus* | T | Unlikely | This species occurs on barrier islands, mainly on coastal overwash flats at the accreting ends of the islands and lower foredunes and on ocean beaches above mean high tide. |

**Notes**: E = Endangered; T= Threatened (if not preceded by “S” or “F”, state and federal designation are the same)

## Table 2-3. Assessment and Measurement Endpoints

| Assessment Endpoint(s) | Measurement Endpoint |
|---|---|
| **Macroinvertebrate Community** | |
| Survival, growth, and reproduction of the soil macroinvertebrate community. | Comparison of COI concentrations in soil to ecotoxicity benchmarks for soil macroinvertebrates. |
| Survival, growth, and reproduction of the benthic macroinvertebrate community. | Comparison of COI concentrations in sediment and surface water/pore water to ecotoxicity benchmarks for benthic macroinvertebrates. |

| Assessment Endpoint(s) | Measurement Endpoint |
|---|---|
| **Avian Community** | |
| Survival, growth, and reproduction of the avian invertivore community. | Comparison of modeled daily doses to a toxicity reference value (TRV). |
| Survival, growth, and reproduction of the avian herbivore community. | |
| Survival, growth, and reproduction of the avian carnivore/piscivore community. | |
| **Mammalian Community** | |
| Survival, growth, and reproduction of the mammalian invertivore community. | Comparison of modeled daily doses to a TRV. |
| Survival, growth, and reproduction of the mammalian herbivore community. | |
| Survival, growth, and reproduction of the mammalian carnivore/piscivore community. | |

**Notes:**

% = Percent
CASRN = Chemical Abstracts Service Registry Number
COPEC = Chemical of Potential Ecological Concern
ft bgs = feet below gound surface
J = Estimated Concentration
LOQ = Limit of Quantiation
MDC = Maximum Detected Concentration
mg/kg = milligram per kilogram
N/A = Not Applicable
ND = Non-Detect or Not Detected
USEPA = United States Environmental Protection Agency

(1) Detection limits are adjusted by their laboratory dilution factors to provide the undiluted LOQ.
(2) Chemicals with a 0% frequency of detect will not be retained for wildlife food chain/dose rate modeling; uncertainty due to LOQs exceeding wildlife-based ESVs will be discussed within the text.

**Table 2**
**Direct Contact Evaluation and Preliminary Wildlife Screening (Western AOC; Surface Soil, 0 - 2 feet)**
**Reasonable Maximum Exposure**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

**Scenario Timeframe:** Current and Future
**Medium:** Soil
**Exposure Medium:** Soil
**Exposure Point:** Soil (0 – 2 ft)

**Notes:**

% = Percent
CASRN = Chemical Abstracts Service Registry Number
COPEC = Chemical of Potential Ecological Concern
ft bgs = feet below gound surface
LOQ = Limit of Quantiation
MDC = Maximum Detected Concentration
mg/kg = milligram per kilogram
N/A = Not Applicable
ND = Non-Detect or Not Detected
USEPA = United States Environmental Protection Agency

(1) Detection limits are adjusted by their laboratory dilution factors to provide the undiluted LOQ.
(2) Chemicals with a 0% frequency of detect will not be retained for wildlife food chain/dose rate modeling; uncertainty due to LOQs exceeding wildlife-based ESVs will be discussed within the text.

J = Estimated Concentration
LOQ = Limit of Quantiation
MDC = Maximum Detected Concentration
mg/kg = milligram per kilogram
N/A = Not Applicable
ND = Non-Detect or Not Detected
USEPA = United States Environmental Protection Agency

(1) Detection limits are adjusted by their laboratory dilution factors to provide the undiluted LOQ.
(2) Chemicals with a 0% frequency of detect will not be retained for wildlife food chain/dose rate modeling; uncertainty due to LOQs exceeding wildlife-based ESVs will be discussed within the text.

**Table 4**
**Direct Contact Evaluation and Preliminary Wildlife Screening (Southern AOC; Surface Soil, 0 - 2 feet)**
**Reasonable Maximum Exposure**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

**Scenario Timeframe:** Current and Future
**Medium:** Soil
**Exposure Medium:** Soil
**Exposure Point:** Soil (0 – 2 ft)

**Notes:**

% = Percent
CASRN = Chemical Abstracts Service Registry Number
COPEC = Chemical of Potential Ecological Concern
ft bgs = feet below gound surface
J = Estimated Concentration
LOQ = Limit of Quantiation
MDC = Maximum Detected Concentration
mg/kg = milligram per kilogram
N/A = Not Applicable
ND = Non-Detect or Not Detected
USEPA = United States Environmental Protection Agency

(1) Detection limits are adjusted by their laboratory dilution factors to provide the undiluted LOQ.
(2) Chemicals with a 0% frequency of detect will not be retained for wildlife food chain/dose rate modeling; uncertainty due to LOQs exceeding wildlife-based ESVs will be discussed within the text.

**Table 5**
**Direct Contact Evaluation and Preliminary Wildlife Screening (Upgradient Drainage; Sediment)**
**Reasonable Maximum Exposure**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

**Scenario Timeframe:** Current and Future
**Medium:** Sediment
**Exposure Medium:** Sediment
**Exposure Point:** Sediment

**Notes:**

% = Percent
CASRN = Chemical Abstracts Service Registry Number
COPEC = Chemical of Potential Ecological Concern
ft bgs = feet below gound surface
J = Estimated Concentration
LOQ = Limit of Quantiation
MDC = Maximum Detected Concentration
mg/kg = milligram per kilogram
N/A = Not Applicable
ND = Non-Detect or Not Detected
USEPA = United States Environmental Protection Agency

(1) Detection limits are adjusted by their laboratory dilution factors to provide the undiluted LOQ.
(2) Chemicals with a 0% frequency of detect will not be retained for wildlife food chain/dose rate modeling; uncertainty due to LOQs exceeding wildlife-based ESVs will be discussed within the text.

**Notes:**

% = Percent
CASRN = Chemical Abstracts Service Registry Number
COPEC = Chemical of Potential Ecological Concern
ft bgs = feet below gound surface
J = Estimated Concentration
LOQ = Limit of Quantiation
MDC = Maximum Detected Concentration
mg/kg = milligram per kilogram
N/A = Not Applicable
ND = Non-Detect or Not Detected
USEPA = United States Environmental Protection Agency

(1) Detection limits are adjusted by their laboratory dilution factors to provide the undiluted LOQ.
(2) Chemicals with a 0% frequency of detect will not be retained for wildlife food chain/dose rate modeling; uncertainty due to LOQs exceeding wildlife-based ESVs will be discussed within the text.

**Notes:**

% = Percent
CASRN = Chemical Abstracts Service Registry Number
COPEC = Chemical of Potential Ecological Concern
ft bgs = feet below gound surface
J = Estimated Concentration
LOQ = Limit of Quantiation
MDC = Maximum Detected Concentration
mg/kg = milligram per kilogram
N/A = Not Applicable
ND = Non-Detect or Not Detected
USEPA = United States Environmental Protection Agency

(1) Detection limits are adjusted by their laboratory dilution factors to provide the undiluted LOQ.
(2) Chemicals with a 0% frequency of detect will not be retained for wildlife food chain/dose rate modeling; uncertainty due to LOQs exceeding wildlife-based ESVs will be discussed within the text.

**Notes:**

% = Percent
CASRN = Chemical Abstracts Service Registry Number
COPEC = Chemical of Potential Ecological Concern
ft bgs = feet below gound surface
J = Estimated Concentration
LOQ = Limit of Quantiation
MDC = Maximum Detected Concentration
N/A = Not Applicable
ND = Non-Detect or Not Detected
µg/L = micrograms per liter
USEPA = United States Environmental Protection Agency

(1) Detection limits are adjusted by their laboratory dilution factors to provide the undiluted LOQ.
(2) Chemicals with a 0% frequency of detect will not be retained for wildlife food chain/dose rate modeling; uncertainty due to LOQs exceeding wildlife-based ESVs will be discussed within the text.

# Attachment B

**Notes:**

ha = hectare; invert. = invertebrates; kg = kilogram; % = percent; USEPA = United States Environmental Protection Agency

(a) Estimated food ingestion rate (kg/day dry weight) for granivorous birds = (0.088*[Body Weight in kg*1000]^0.891)/1000

(b) For terrestrial receptors, the contribution of surface water was considered negligible with prey items consisting of each receptors primary source of dietary water.

(c) Estimated based on a soil consumption rate of mourning dove of 13.9% (USEPA, 2007).

(d) Estimated food ingestion rate (kg/day dry weight) for insectivorous birds = (0.540*[Body Weight in kg*1000]^0.705)/1000

(e) Estimated based on a soil consumption rate of woodcock of 10.4% (Beyer et al., 1994).

(f) Estimated food ingestion rate (kg/day dry weight) for carnivorous birds = (0.849*[Body Weight in kg*1000]^0.663)/1000

(g) For aquatic and semi-aquatic receptors, ingestion rate of surface water from the site (if available) was modeled based on the following equations developed by Caulder and Braun (1983) and as presented in Sample and Suter (1994):
Water ingestion rate (L/day) for birds = 0.059*(Body Weight in kg)^0.67
Water ingestion rate (L/day) for mammals = 0.099*(Body Weight in kg)^0.90

(h) Estimated based on a soil consumption rate of blue-winged teal of <2.0% (Beyer et al., 1994).

(i) Estimated food ingestion rate (kg/day dry weight) for mammalian insectivores = (0.373*[Body Weight in kg*1000]^0.622)/1000

(j) Estimated food ingestion rate (kg/day dry weight) for mammalian carnivores = (0.153*[Body Weight in kg*1000]^0.834)/1000

| Bis(2-Ethylhexyl)phthalate | 7.6 | 0.0558 | Regression | 0.00278 | USEPA (2007) (c) | Modeled | 11.9 | USEPA (2007) (d) | 1 | 11.9 | Travis and Arms (1988) (e) |

**Notes:**

BAF = Bioaccumulation Factor; EPC = Exposure Point Concentration; kg = kilogram; $K_{ow}$ = n-octanol/water partitioning coefficient; log = base-10; mg = milligram; UCL = Upper Confidence Limit; USEPA = United States Environmental Protection Agency

(a) Plant tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]). Slopes (B1) and intercepts (B0) are as follows:

| Chemical | BO | B1 | Data Source for Model |
|---|---|---|---|
| Mercury | -0.996 | 0.544 | Bechtel-Jacobs (1998) |

(b) Soil invertebrate tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]). Slopes (B1) and intercepts (B0) are as follows:

| Chemical | BO | B1 | Data Source for Model |
|---|---|---|---|
| Mercury | 0.0781 | 0.3369 | Sample et al. (1998a) |

(c) Plant tissue concentrations (mg/kg dry weight) calculated based on a regression model developed for non-ionic, organic compounds (USEPA, 2007), where:
log(BAF) = -0.4057 x log $K_{ow}$ + 1.781; and log $K_{ow}$ = 3 – 8

(d) USEPA (2007) suggests using a soil-to-earthworm model presented for non-ionic, organics without established uptake models, where:
$C_{earthworm} = (10^{0.87} \times \log K_{ow} - 2.0])/CF_{ww\text{-}dw} \times C_{soil} \times 1/(f_{oc} \times K_{oc})$; and log $K_{ow}$ = 2 – 8, $f_{oc}$ = 1%, and $CF_{ww\text{-}dw}$ (convert wet weight to dry weight) = 16%

(e) For organics without established uptake models, food-to-tissue uptake was estimated using biotransfer coefficients presented in Travis and Arms (1988) where:
$BAF_{small\ mammals} = 10^{(-7.6 + \log K_{ow})}$
When modeling small mammal tissue concentrations, the highest food source concentration (either plants or invertebrates) was multiplied by $BAF_{small\ mammal}$ to remain protective of all trophic levels.

**Table 5**
**Soil Bioaccumulation Factors and Estimated Concentrations in Prey Items (Southern AOC)**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

| Analyte | log $K_{ow}$ | Maximum Soil EPC (mg/kg, dry weight) | Estimated Concentrations in Dietary Items of Terrestrial Receptors (mg/kg, dry weight) | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | Terrestrial Plants | | | Soil Invertebrates | | | Small Mammals | | |
| | | | $BAF_{plants}$ | Estimated Concentration | Reference | $BAF_{invertebrates}$ | Estimated Concentration | Reference | $BAF_{mammals}$ | Estimated Concentration | Reference |

**Notes:**

BAF = Bioaccumulation Factor; EPC = Exposure Point Concentration; kg = kilogram; $K_{ow}$ = n-octanol/water partitioning coefficient; log = base-10; mg = milligram; UCL = Upper Confidence Limit; USEPA = United States Environmental Protection Agency

(a) Plant tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]). Slopes (B1) and intercepts (B0) are as follows:

| Chemical | BO | B1 | Data Source for Model |
|---|---|---|---|
| Antimony | -3.233 | 0.937 | USEPA (2007) |
| Cadmium | -0.476 | 0.546 | Bechtel-Jacobs (1998) |
| Copper | 0.669 | 0.394 | Bechtel-Jacobs (1998) |
| Lead | -1.328 | 0.561 | Bechtel-Jacobs (1998) |
| Mercury | -0.996 | 0.544 | Bechtel-Jacobs (1998) |
| Nickel | -2.224 | 0.748 | Bechtel-Jacobs (1998) |
| Selenium | -0.678 | 1.104 | Bechtel-Jacobs (1998) |
| Zinc | 1.575 | 0.555 | Bechtel-Jacobs (1998) |

(b) Not available; bioaccumulation factor is assumed to be 1.0 USEPA (2007)

(c) USEPA (2007) suggests using a diet-to-beef model presented in Baes et al. (1984) for inorganics without established uptake models, where:
$BAF_{soil\text{-}to\text{-}beef} = BAF_{soil\text{-}to\text{-}diet\ (plant)} \times 50$ (cattle food intake) x $F_f$ (diet-to-biota factor)

Diet-to-biota factors presented in Baes et al. (1984) are listed below:

| Chemical | $F_f$ |
|---|---|
| Antimony | 0.001 |

(d) Soil invertebrate tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]). Slopes (B1) and intercepts (B0) are as follows:

| Chemical | BO | B1 | Data Source for Model |
|---|---|---|---|
| Aroclor 1260 | 1.41 | 1.36 | Sample et al. (1998a) |
| Cadmium | 1.21 | 0.66 | Neuhauser et al. (1995) |
| Copper | 1.675 | 0.264 | Sample et al. (1998a) |
| Lead | -0.218 | 0.807 | Sample et al. (1998a) |
| Mercury | 0.0781 | 0.3369 | Sample et al. (1998a) |
| Selenium | -0.075 | 0.733 | Sample et al. (1998a) |
| Zinc | 4.449 | 0.328 | Sample et al. (1998a) |

(e) Small mammal tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]).
If multiple trophic-based models were presented, the best fitting model was applied. Slopes (B1) and intercepts (B0) are as follows:

| Chemical | BO | B1 | Data Source for Model |
|---|---|---|---|
| Cadmium | -1.2571 | 0.4723 | Sample et al. (1998b) |
| Chromium | -1.4599 | 0.7338 | Sample et al. (1998b) |
| Copper | 2.1042 | 0.1783 | Sample et al. (1998b) |
| Lead | -0.6114 | 0.5181 | Sample et al. (1998b) |
| Nickel | -0.2464 | 0.4658 | Sample et al. (1998b) |
| Selenium | -0.4158 | 0.3764 | Sample et al. (1998b) |
| Zinc | 4.2479 | 0.1324 | Sample et al. (1998b) |

(f) Plant tissue concentrations (mg/kg dry weight) calculated based on a regression model developed for non-ionic, organic compounds (USEPA, 2007), where:
$\log(BAF) = -0.4057 \times \log K_{ow} + 1.781$; and $\log K_{ow} = 3 – 8$

(g) USEPA (2007) suggests using a soil-to-earthworm model presented for non-ionic, organics without established uptake models, where:
$C_{earthworm} = (10^{[0.87 \times \log K_{ow} - 2.0]})/CF_{ww\text{-}dw} \times C_{soil} \times 1/(f_{oc} \times K_{oc})$; and $\log K_{ow} = 2 – 8$, $f_{oc}$ = 1%, and $CF_{ww\text{-}dw}$ (convert wet weight to dry weight) = 16%

**Table 5**
**Soil Bioaccumulation Factors and Estimated Concentrations in Prey Items (Southern AOC)**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

| Analyte | log $K_{ow}$ | Maximum Soil EPC (mg/kg, dry weight) | Estimated Concentrations in Dietary Items of Terrestrial Receptors (mg/kg, dry weight) | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | Terrestrial Plants | | | Soil Invertebrates | | | Small Mammals | | |
| | | | $BAF_{plants}$ | Estimated Concentration | Reference | $BAF_{invertebrates}$ | Estimated Concentration | Reference | $BAF_{mammals}$ | Estimated Concentration | Reference |

(h) For organics without established uptake models, food-to-tissue uptake was estimated using biotransfer coefficients presented in Travis and Arms (1988) where:

$BAF_{small\ mammals} = 10^{(-7.6 + \log K_{ow})}$

When modeling small mammal tissue concentrations, the highest food source concentration (either plants or invertebrates) was multiplied by $BAF_{small\ mammal}$ to remain protective of all trophic levels.

(i) PCBs not likely to be taken up by plants; bioaccumulation expected to be negligible (USEPA 1997).

**Table 9**
**Terrestrial Dose Rate Model Output (Northern AOC)**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

**Notes:**
bw/d = body weight per day; COPEC = Chemical of Potential Ecological Concern; EPC = Exposure Point Concentration; Invert. = Invertebrates;
kg = kilogram; LOAEL = Lowest Observable Adverse Effect Level; mg = milligram; N/A = Not Available; NOAEL = No Observable Adverse Effect Level;
TRV = toxicity reference value; -- = not evaluated

(a) Dietary dose calculated as:

$$EDD_{diet} = \frac{IR_{diet} \times \sum(B[S]AF \times C_{soil} \times DF_i) \times AUF}{BW}$$

(b) Substrate dose calculated as:

$$EDD_{substrate} = \frac{IR_{substrate} \times C_{substrate} \times AUF}{BW}$$

(c) Total dose calculated as:

$$EDD_{total} = EDD_{diet} + EDD_{substrate}$$

**Where:**

| | |
|---|---|
| $EDD_{diet}$ | = Dose of COPEC obtained from the diet (mg COPEC/kg receptor body weight-day) |
| $IR_{diet}$ | = Ingestion rate of food (kg food ingested per day, dry weight) |
| B(S)AF | = Bioaccumulation factor (BAF) or biota-sediment accumulation factor (BSAF), specific to prey type and COPEC (kg substrate/kg food, dry weight) |
| $C_{soil}$ | = COPEC concentration in soil (mg COPEC/kg soil, dry weight) |
| $DF_i$ | = Dietary fraction of food item *i* |
| AUF | = Area use factor accounts for receptor home range |
| BW | = Body weight of the receptor, wet weight |
| $EDD_{substrate}$ | = Dose of COPEC obtained from substrate (mg COPEC/kg receptor body weight-day) |
| $IR_{substrate}$ | = Incidental Ingestion rate of substrate (kg substrate ingested per day, dry weight) |
| $C_{substrate}$ | = COPEC concentration in substrate (mg COPEC/kg substrate, dry weight) |

**Table 10**
**Terrestrial Dose Rate Model Output (Western AOC)**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

**Notes:**
bw/d = body weight per day; COPEC = Chemical of Potential Ecological Concern; EPC = Exposure Point Concentration; Invert. = Invertebrates;
kg = kilogram; LOAEL = Lowest Observable Adverse Effect Level; mg = milligram; N/A = Not Available; NOAEL = No Observable Adverse Effect Level;
TRV = toxicity reference value; -- = not evaluated

(a) Dietary dose calculated as:

$$EDD_{diet} = \frac{IR_{diet} \times \sum(B[S]AF \times C_{soil} \times DF_i) \times AUF}{BW}$$

(b) Substrate dose calculated as:

$$EDD_{substrate} = \frac{IR_{substrate} \times C_{substrate} \times AUF}{BW}$$

(c) Total dose calculated as:

$$EDD_{total} = EDD_{diet} + EDD_{substrate}$$

**Where:**

| | |
|---|---|
| $EDD_{diet}$ | = Dose of COPEC obtained from the diet (mg COPEC/kg receptor body weight-day) |
| $IR_{diet}$ | = Ingestion rate of food (kg food ingested per day, dry weight) |
| B(S)AF | = Bioaccumulation factor (BAF) or biota-sediment accumulation factor (BSAF), specific to prey type and COPEC (kg substrate/kg food, dry weight) |
| $C_{soil}$ | = COPEC concentration in soil (mg COPEC/kg soil, dry weight) |
| $DF_i$ | = Dietary fraction of food item *i* |
| AUF | = Area use factor accounts for receptor home range |
| BW | = Body weight of the receptor, wet weight |
| $EDD_{substrate}$ | = Dose of COPEC obtained from substrate (mg COPEC/kg receptor body weight-day) |
| $IR_{substrate}$ | = Incidental Ingestion rate of substrate (kg substrate ingested per day, dry weight) |
| $C_{substrate}$ | = COPEC concentration in substrate (mg COPEC/kg substrate, dry weight) |

**Table 11**
**Terrestrial Dose Rate Model Output (Central AOC)**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

**Notes:**
bw/d = body weight per day; COPEC = Chemical of Potential Ecological Concern; EPC = Exposure Point Concentration; Invert. = Invertebrates;
kg = kilogram; LOAEL = Lowest Observable Adverse Effect Level; mg = milligram; N/A = Not Available; NOAEL = No Observable Adverse Effect Level;
TRV = toxicity reference value; -- = not evaluated

(a) Dietary dose calculated as:

$$EDD_{diet} = \frac{IR_{diet} \times \sum(B[S]AF \times C_{soil} \times DF_i) \times AUF}{BW}$$

(b) Substrate dose calculated as:

$$EDD_{substrate} = \frac{IR_{substrate} \times C_{substrate} \times AUF}{BW}$$

(c) Total dose calculated as:

$$EDD_{total} = EDD_{diet} + EDD_{substrate}$$

**Where:**

| | |
|---|---|
| $EDD_{diet}$ | = Dose of COPEC obtained from the diet (mg COPEC/kg receptor body weight-day) |
| $IR_{diet}$ | = Ingestion rate of food (kg food ingested per day, dry weight) |
| B(S)AF | = Bioaccumulation factor (BAF) or biota-sediment accumulation factor (BSAF), specific to prey type and COPEC (kg substrate/kg food, dry weight) |
| $C_{soil}$ | = COPEC concentration in soil (mg COPEC/kg soil, dry weight) |
| $DF_i$ | = Dietary fraction of food item *i* |
| AUF | = Area use factor accounts for receptor home range |
| BW | = Body weight of the receptor, wet weight |
| $EDD_{substrate}$ | = Dose of COPEC obtained from substrate (mg COPEC/kg receptor body weight-day) |
| $IR_{substrate}$ | = Incidental Ingestion rate of substrate (kg substrate ingested per day, dry weight) |
| $C_{substrate}$ | = COPEC concentration in substrate (mg COPEC/kg substrate, dry weight) |

**Table 12**
**Terrestrial Dose Rate Model Output (Southern AOC)**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

**Notes:**
bw/d = body weight per day; COPEC = Chemical of Potential Ecological Concern; EPC = Exposure Point Concentration; Invert. = Invertebrates;
kg = kilogram; LOAEL = Lowest Observable Adverse Effect Level; mg = milligram; N/A = Not Available; NOAEL = No Observable Adverse Effect Level;
TRV = toxicity reference value; -- = not evaluated

(a) Dietary dose calculated as:

$$EDD_{diet} = \frac{IR_{diet} \times \sum(B[S]AF \times C_{soil} \times DF_i) \times AUF}{BW}$$

(b) Substrate dose calculated as:

$$EDD_{substrate} = \frac{IR_{substrate} \times C_{substrate} \times AUF}{BW}$$

(c) Total dose calculated as:

$$EDD_{total} = EDD_{diet} + EDD_{substrate}$$

**Where:**

| | |
|---|---|
| $EDD_{diet}$ | = Dose of COPEC obtained from the diet (mg COPEC/kg receptor body weight-day) |
| $IR_{diet}$ | = Ingestion rate of food (kg food ingested per day, dry weight) |
| B(S)AF | = Bioaccumulation factor (BAF) or biota-sediment accumulation factor (BSAF), specific to prey type and COPEC (kg substrate/kg food, dry weight) |
| $C_{soil}$ | = COPEC concentration in soil (mg COPEC/kg soil, dry weight) |
| $DF_i$ | = Dietary fraction of food item *i* |
| AUF | = Area use factor accounts for receptor home range |
| BW | = Body weight of the receptor, wet weight |
| $EDD_{substrate}$ | = Dose of COPEC obtained from substrate (mg COPEC/kg receptor body weight-day) |
| $IR_{substrate}$ | = Incidental Ingestion rate of substrate (kg substrate ingested per day, dry weight) |
| $C_{substrate}$ | = COPEC concentration in substrate (mg COPEC/kg substrate, dry weight) |

**Table 13**
**Aquatic and Semi-Aquatic Dose Rate Model Output (Upgradient Drainage)**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

**Notes:**
bw/d = body weight per day; COPEC = Chemical of Potential Ecological Concern; EPC = Exposure Point Concentration; Invert. = Invertebrates;
kg = kilogram; LOAEL = Lowest Observable Adverse Effect Level; mg = milligram; N/A = Not Available; NOAEL = No Observable Adverse Effect Level;
TRV = toxicity reference value; -- = not evaluated

(a) Dietary dose calculated as:

$$EDD_{diet} = \frac{IR_{diet} \times \sum(B[S]AF \times C_{soil} \times DF_i) \times AUF}{BW}$$

(b) Substrate dose calculated as:

$$EDD_{substrate} = \frac{IR_{substrate} \times C_{substrate} \times AUF}{BW}$$

(c) Total dose calculated as:

$$EDD_{total} = EDD_{diet} + EDD_{substrate}$$

**Where:**

| | |
|---|---|
| $EDD_{diet}$ | = Dose of COPEC obtained from the diet (mg COPEC/kg receptor body weight-day) |
| $IR_{diet}$ | = Ingestion rate of food (kg food ingested per day, dry weight) |
| B(S)AF | = Bioaccumulation factor (BAF) or biota-sediment accumulation factor (BSAF), specific to prey type and COPEC (kg substrate/kg food, dry weight) |
| $C_{soil}$ | = COPEC concentration in soil (mg COPEC/kg soil, dry weight) |
| $DF_i$ | = Dietary fraction of food item *i* |
| AUF | = Area use factor accounts for receptor home range |
| BW | = Body weight of the receptor, wet weight |
| $EDD_{substrate}$ | = Dose of COPEC obtained from substrate (mg COPEC/kg receptor body weight-day) |
| $IR_{substrate}$ | = Incidental Ingestion rate of substrate (kg substrate ingested per day, dry weight) |
| $C_{substrate}$ | = COPEC concentration in substrate (mg COPEC/kg substrate, dry weight) |

| | | | |
|---|---|---|---|
| 95% Student's-t UCL | 86.33 | or 95% Modified-t UCL | 87.14 |
| or 95% H-UCL | 91.08 | | |

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.

H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.

It is therefore recommended to avoid the use of H-statistic based 95% UCLs.

Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

| | | | |
| When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test | | | |
| When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL | | | |
| | | | |
| Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL. | | | |
| Recommendations are based upon data size, data distribution, and skewness. | | | |
| These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006). | | | |
| However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician. | | | |

**ProUCL 5.1 Output**

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

**Suggested UCL to Use**

| | | | |
|---|---|---|---|
| 95% Student's-t UCL | 12.4 | or 95% Modified-t UCL | 12.45 |
| or 95% H-UCL | 12.88 | | |

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.

H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.

It is therefore recommended to avoid the use of H-statistic based 95% UCLs.

Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

| GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs | | | |
| GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20) | | | |
| For such situations, GROS method may yield incorrect values of UCLs and BTVs | | | |
| This is especially true when the sample size is small. | | | |
| For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates | | | |

**Suggested UCL to Use**

| 95% KM (t) UCL | 0.0531 | | |
|---|---|---|---|

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

|---|---|---|---|
| Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use | | | |
| guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest. | | | |
| For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012). | | | |
| Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1 | | | |

| 95% Chebyshev (Mean, Sd) UCL | 837.1 | | |

**Attachment C**
**ProUCL 5.1 Output**

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

| | | | |
| **ProUCL computes and outputs H-statistic based UCLs for historical reasons only.** | | | |
| **H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.** | | | |
| **It is therefore recommended to avoid the use of H-statistic based 95% UCLs.** | | | |
| **Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.** | | | |

**Notes:**

Red text indicate Step 3a refinements; ha = hectare; invert. = invertebrates; kg = kilogram; % = percent; USEPA = United States Environmental Protection Agency

(a) Estimated food ingestion rate (kg/day dry weight) for granivorous birds = (0.088*[Body Weight in kg*1000]^0.891)/1000

(b) For terrestrial receptors, the contribution of surface water was considered negligible with prey items consisting of each receptors primary source of dietary water.

(c) Estimated based on a soil consumption rate of mourning dove of 13.9% (USEPA, 2007).

(d) Estimated food ingestion rate (kg/day dry weight) for insectivorous birds = (0.540*[Body Weight in kg*1000]^0.705)/1000

(e) Estimated based on a soil consumption rate of woodcock of 10.4% (Beyer et al., 1994).

(f) Estimated food ingestion rate (kg/day dry weight) for carnivorous birds = (0.849*[Body Weight in kg*1000]^0.663)/1000

(g) For aquatic and semi-aquatic receptors, ingestion rate of surface water from the site (if available) was modeled based on the following equations developed by Caulder and Braun (1983) and as presented in Sample and Suter (1994):
Water ingestion rate (L/day) for birds = 0.059*(Body Weight in kg)^0.67
Water ingestion rate (L/day) for mammals = 0.099*(Body Weight in kg)^0.90

(h) Estimated based on a soil consumption rate of blue-winged teal of <2.0% (Beyer et al., 1994).

(i) Estimated food ingestion rate (kg/day dry weight) for mammalian insectivores = (0.373*[Body Weight in kg*1000]^0.622)/1000

(j) Estimated food ingestion rate (kg/day dry weight) for mammalian carnivores = (0.153*[Body Weight in kg*1000]^0.834)/1000

| **Semi-volatile Organic Compounds (SVOCs)** | | | | | | | | | | | |
| Bis(2-Ethylhexyl)phthalate | 7.6 | 0.0558 | Regression | 0.00278 | USEPA (2007) (a) | Modeled | 11.9 | USEPA (2007) (b) | 1 | 11.9 | Travis and Arms (1988) (c) |

**Notes:**

BAF = Bioaccumulation Factor; EPC = Exposure Point Concentration; kg = kilogram; $K_{ow}$ = n-octanol/water partitioning coefficient; log = base-10; mg = milligram; UCL = Upper Confidence Limit; USEPA = United States Environmental Protection Agency

(a) Plant tissue concentrations (mg/kg dry weight) calculated based on a regression model developed for non-ionic, organic compounds (USEPA, 2007), where:
$\log(BAF) = -0.4057 \times \log K_{ow} + 1.781$; and $\log K_{ow} = 3 – 8$

(b) USEPA (2007) suggests using a soil-to-earthworm model presented for non-ionic, organics without established uptake models, where:
$C_{earthworm} = (10^{[0.87 \times \log K_{ow} - 2.0]})/CF_{ww\text{-}dw} \times C_{soil} \times 1/(f_{oc} \times K_{oc})$; and $\log K_{ow} = 2 – 8$, $f_{oc}$ = 1%, and $CF_{ww\text{-}dw}$ (convert wet weight to dry weight) = 16%

(c) For organics without established uptake models, food-to-tissue uptake was estimated using biotransfer coefficients presented in Travis and Arms (1988) where:
$BAF_{small\ mammals} = 10^{(-7.6 + \log K_{ow})}$
When modeling small mammal tissue concentrations, the highest food source concentration (either plants or invertebrates) was multiplied by $BAF_{small\ mammal}$ to remain protective of all trophic levels.

BAF = Bioaccumulation Factor; EPC = Exposure Point Concentration; kg = kilogram; $K_{ow}$ = n-octanol/water partitioning coefficient; log = base-10; mg = milligram; UCL = Upper Confidence Limit; USEPA = United States Environmental Protection Agency

(a) Plant tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]). Slopes (B1) and intercepts (B0) are as follows:

| Chemical | BO | B1 | Data Source for Model |
|---|---|---|---|
| Lead | -1.328 | 0.561 | Bechtel-Jacobs (1998) |
| Nickel | -2.224 | 0.748 | Bechtel-Jacobs (1998) |
| Selenium | -0.678 | 1.104 | Bechtel-Jacobs (1998) |
| Zinc | 1.575 | 0.555 | Bechtel-Jacobs (1998) |
| Total HMW PAHs | -1.7026 | 0.9469 | USEPA (2007) |

(b) Soil invertebrate tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]). Slopes (B1) and intercepts (B0) are as follows:

| Chemical | BO | B1 | Data Source for Model |
|---|---|---|---|
| Lead | -0.218 | 0.807 | Sample et al. (1998a) |
| Selenium | -0.075 | 0.733 | Sample et al. (1998a) |
| Zinc | 4.449 | 0.328 | Sample et al. (1998a) |

(c) Small mammal tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]).
If multiple trophic-based models were presented, the best fitting model was applied. Slopes (B1) and intercepts (B0) are as follows:

| Chemical | BO | B1 | Data Source for Model |
|---|---|---|---|
| Chromium | -1.4599 | 0.7338 | Sample et al. (1998b) |
| Lead | -0.6114 | 0.5181 | Sample et al. (1998b) |

**Table 4**
**Refined Soil Bioaccumulation Factors and Estimated Concentrations in Prey Items (Central AOC)**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

| Analyte | log $K_{ow}$ | Refined Soil EPC (mg/kg, dry weight) | Estimated Concentrations in Dietary Items of Terrestrial Receptors (mg/kg, dry weight) | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | Terrestrial Plants | | | Soil Invertebrates | | | Small Mammals | | |
| | | | $BAF_{plants}$ | Estimated Concentration | Reference | $BAF_{invertebrates}$ | Estimated Concentration | Reference | $BAF_{mammals}$ | Estimated Concentration | Reference |
| Nickel | -0.2464 | 0.4658 | Sample et al. (1998b) | | | | | | | | |
| Selenium | -0.4158 | 0.3764 | Sample et al. (1998b) | | | | | | | | |
| Zinc | 4.2479 | 0.1324 | Sample et al. (1998b) | | | | | | | | |

(d) Plant tissue concentrations (mg/kg dry weight) calculated based on a regression model developed for non-ionic, organic compounds (USEPA, 2007), where:
$\log(BAF) = -0.4057 \times \log K_{ow} + 1.781$; and $\log K_{ow} = 3 – 8$

(e) USEPA (2007) suggests using a soil-to-earthworm model presented for non-ionic, organics without established uptake models, where:
$C_{earthworm} = (10^{[0.87 \times \log K_{ow} - 2.0]})/CF_{ww-dw} \times C_{soil} \times 1/(f_{oc} \times K_{oc})$; and $\log K_{ow} = 2 – 8$, $f_{oc} = 1\%$, and $CF_{ww-dw}$ (convert wet weight to dry weight) = 16%

(f) For organics without established uptake models, food-to-tissue uptake was estimated using biotransfer coefficients presented in Travis and Arms (1988) where:
$BAF_{small\ mammals} = 10^{(-7.6 + \log K_{ow})}$
When modeling small mammal tissue concentrations, the highest food source concentration (either plants or invertebrates) was multiplied by $BAF_{small\ mammal}$ to remain protective of all trophic levels.

(g) Bioaccumulation expected to be minimal due to rapid metabolism of these compounds after ingestion (USEPA, 2007).

| | | | $BAF_{plants}$ | Estimated Concentration | Reference | $BAF_{invertebrates}$ | Estimated Concentration | Reference | $BAF_{mammals}$ | Estimated Concentration | Reference |
| Selenium | -0.678 | 1.104 | Bechtel-Jacobs (1998) | | | | | | | | |
| Zinc | 1.575 | 0.555 | Bechtel-Jacobs (1998) | | | | | | | | |

(b) Not available; bioaccumulation factor is assumed to be 1.0 USEPA (2007)

(c) USEPA (2007) suggests using a diet-to-beef model presented in Baes et al. (1984) for inorganics without established uptake models, where:
$BAF_{soil\text{-}to\text{-}beef} = BAF_{soil\text{-}to\text{-}diet\ (plant)} \times 50$ (cattle food intake) $\times F_f$ (diet-to-biota factor)

Diet-to-biota factors presented in Baes et al. (1984) are listed below:

| Chemical | $F_f$ |
|---|---|
| Antimony | 0.001 |

(d) Soil invertebrate tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]). Slopes (B1) and intercepts (B0) are as follows:

| Chemical | BO | B1 | Data Source for Model |
|---|---|---|---|
| Cadmium | 1.21 | 0.66 | Neuhauser et al. (1995) |
| Copper | 1.675 | 0.264 | Sample et al. (1998a) |
| Lead | -0.218 | 0.807 | Sample et al. (1998a) |
| Selenium | -0.075 | 0.733 | Sample et al. (1998a) |
| Zinc | 4.449 | 0.328 | Sample et al. (1998a) |

(e) Small mammal tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]).
If multiple trophic-based models were presented, the best fitting model was applied. Slopes (B1) and intercepts (B0) are as follows:

| Chemical | BO | B1 | Data Source for Model |
|---|---|---|---|
| Cadmium | -1.2571 | 0.4723 | Sample et al. (1998b) |
| Chromium | -1.4599 | 0.7338 | Sample et al. (1998b) |
| Copper | 2.1042 | 0.1783 | Sample et al. (1998b) |
| Lead | -0.6114 | 0.5181 | Sample et al. (1998b) |
| Nickel | -0.2464 | 0.4658 | Sample et al. (1998b) |
| Selenium | -0.4158 | 0.3764 | Sample et al. (1998b) |
| Zinc | 4.2479 | 0.1324 | Sample et al. (1998b) |

(f) Plant tissue concentrations (mg/kg dry weight) calculated based on a regression model developed for non-ionic, organic compounds (USEPA, 2007), where:
$\log(BAF) = -0.4057 \times \log K_{ow} + 1.781$; and $\log K_{ow} = 3 – 8$

(g) USEPA (2007) suggests using a soil-to-earthworm model presented for non-ionic, organics without established uptake models, where:
$C_{earthworm} = (10^{[0.87 \times \log K_{ow} - 2.0]})/CF_{ww\text{-}dw} \times C_{soil} \times 1/(f_{oc} \times K_{oc})$; and $\log K_{ow} = 2 – 8$, $f_{oc} = 1\%$, and $CF_{ww\text{-}dw}$ (convert wet weight to dry weight) = 16%

(h) For organics without established uptake models, food-to-tissue uptake was estimated using biotransfer coefficients presented in Travis and Arms (1988) where:
$BAF_{small\ mammals} = 10^{(-7.6 + \log K_{ow})}$

When modeling small mammal tissue concentrations, the highest food source concentration (either plants or invertebrates) was multiplied by $BAF_{small\ mammal}$ to remain protective of all trophic levels.

**Notes:**

BSAF = Biota Sediment Accumulation Factor; EPC = Exposure Point Concentration; kg = kilogram; $K_{ow}$ = n-octanol/water partitioning coefficient; log = base-10; mg = milligram;
USEPA = United States Environmental Protection Agency

(a) Median BSAF for non-depurated invertebrates determined by Bechtel and Jacobs (1998)

(b) Sediment-to-fish BSAFs could not be identified; therefore, concentrations in fish were assumed to be equal to concentrations in benthic invertebrates.

(c) Invertebrate concentrations (mg/kg dry weight) calculated based on regression models, where slopes (B1) and intercepts (B0) are as follows:

| Chemical | BO | B1 | Model | Data Source for Model | |
|---|---|---|---|---|---|
| Vanadium | -1.5311 | 0.7219 | y = B0 + B1 * ln([sediment]) | Hamilton and Buhl (2003a,b) | |

(d) For organic constituents, BSAFs were calculated from sediment organic carbon and lipid normalized BSAF, where:
$BSAF_{norm}$ (kg OC / kg lipid) = $Kow^{0.038}$ (DiToro and McGrath 2000) and BSAF (kg OC / kg lipid) = $BSAF_{norm} \times f_{lipid} \times 1/f_{oc}$ ($f_{lipid}$ = 0.052 and 0.25 [intertebrates and fish, respectively] and $f_{oc}$ = 0.01)
$f_{lipid}$ based on the geometric mean % lipid [dw] for all invertebrate groups (benthics) and all vertebrate groups (fish only) within the USACE's BSAF database filtered only for results including biphenyls, dioxins, furans, polycyclic aromatic hydrocarbons, polychlorinated biphenyls, and pesticides/herbicides (USACE, 2017)

**Notes:**

BSAF = Biota Sediment Accumulation Factor; EPC = Exposure Point Concentration; kg = kilogram; $K_{ow}$ = n-octanol/water partitioning coefficient; log = base-10; mg = milligram;
USEPA = United States Environmental Protection Agency

(a) Sediment-to-invertebrate BSAFs could not be identified; therefore, concentrations in benthic invertebrates were assumed to be equal to the sediment EPC.

(b) Sediment-to-fish BSAFs could not be identified; therefore, concentrations in fish were assumed to be equal to concentrations in benthic invertebrates.

(c) Median BSAF for non-depurated invertebrates determined by Bechtel and Jacobs (1998)

(d) Invertebrate concentrations (mg/kg dry weight) calculated based on regression models, where slopes (B1) and intercepts (B0) are as follows:

| Chemical | B0 | B1 | Model | Data Source for Model |
|---|---|---|---|---|
| Selenium | -- | 1.422 | y = B1 * [sediment] | Hamilton and Buhl (2003a,b) |
| Vanadium | -1.5311 | 0.7219 | y = B0 + B1 * ln([sediment]) | Hamilton and Buhl (2003a,b) |

(e) For organic constituents, BSAFs were calculated from sediment organic carbon and lipid normalized BSAF, where:
$BSAF_{norm}$ (kg OC / kg lipid) = $Kow^{-0.038}$ (DiToro and McGrath 2000) and BSAF (kg OC / kg lipid) = $BSAF_{norm} \times f_{lipid} \times 1/f_{oc}$ ($f_{lipid}$ = 0.052 and 0.25 [intertebrates and fish, respectively] and $f_{oc}$ = 0.01)
$f_{lipid}$ based on the geometric mean % lipid [dw] for all invertebrate groups (benthics) and all vertebrate groups (fish only) within the USACE's BSAF database filtered only for results including biphenyls, dioxins, furans, polycyclic aromatic hydrocarbons, polychlorinated biphenyls, and pesticides/herbicides (USACE, 2017)

**Table 8**
**Refined Terrestrial Dose Rate Model Output (Northern AOC)**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

**Notes:**
bw/d = body weight per day; COPEC = Chemical of Potential Ecological Concern; EPC = Exposure Point Concentration; Invert. = Invertebrates;
kg = kilogram; LOAEL = Lowest Observable Adverse Effect Level; mg = milligram; N/A = Not Available; NOAEL = No Observable Adverse Effect Level;
TRV = toxicity reference value; -- = not evaluated

(a) Dietary dose calculated as:

$$EDD_{diet} = \frac{IR_{diet} \times \sum(B[S]AF \times C_{soil} \times DF_i) \times AUF}{BW}$$

(b) Substrate dose calculated as:

$$EDD_{substrate} = \frac{IR_{substrate} \times C_{substrate} \times AUF}{BW}$$

(c) Total dose calculated as:

$$EDD_{total} = EDD_{diet} + EDD_{substrate}$$

**Where:**

| | |
|---|---|
| $EDD_{diet}$ | = Dose of COPEC obtained from the diet (mg COPEC/kg receptor body weight-day) |
| $IR_{diet}$ | = Ingestion rate of food (kg food ingested per day, dry weight) |
| B(S)AF | = Bioaccumulation factor (BAF) or biota-sediment accumulation factor (BSAF), specific to prey type and COPEC (kg substrate/kg food, dry weight) |
| $C_{soil}$ | = COPEC concentration in soil (mg COPEC/kg soil, dry weight) |
| $DF_i$ | = Dietary fraction of food item *i* |
| AUF | = Area use factor accounts for receptor home range |
| BW | = Body weight of the receptor, wet weight |
| $EDD_{substrate}$ | = Dose of COPEC obtained from substrate (mg COPEC/kg receptor body weight-day) |
| $IR_{substrate}$ | = Incidental Ingestion rate of substrate (kg substrate ingested per day, dry weight) |
| $C_{substrate}$ | = COPEC concentration in substrate (mg COPEC/kg substrate, dry weight) |

**Table 10**
**Refined Terrestrial Dose Rate Model Output (Central AOC)**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

**Notes:**
bw/d = body weight per day; COPEC = Chemical of Potential Ecological Concern; EPC = Exposure Point Concentration; Invert. = Invertebrates;
kg = kilogram; LOAEL = Lowest Observable Adverse Effect Level; mg = milligram; N/A = Not Available; NOAEL = No Observable Adverse Effect Level;
TRV = toxicity reference value; -- = not evaluated

(a) Dietary dose calculated as:

$$EDD_{diet} = \frac{IR_{diet} \times \sum(B[S]AF \times C_{soil} \times DF_i) \times AUF}{BW}$$

(b) Substrate dose calculated as:

$$EDD_{substrate} = \frac{IR_{substrate} \times C_{substrate} \times AUF}{BW}$$

(c) Total dose calculated as:

$$EDD_{total} = EDD_{diet} + EDD_{substrate}$$

**Where:**

| | |
|---|---|
| $EDD_{diet}$ | = Dose of COPEC obtained from the diet (mg COPEC/kg receptor body weight-day) |
| $IR_{diet}$ | = Ingestion rate of food (kg food ingested per day, dry weight) |
| B(S)AF | = Bioaccumulation factor (BAF) or biota-sediment accumulation factor (BSAF), specific to prey type and COPEC (kg substrate/kg food, dry weight) |
| $C_{soil}$ | = COPEC concentration in soil (mg COPEC/kg soil, dry weight) |
| $DF_i$ | = Dietary fraction of food item *i* |
| AUF | = Area use factor accounts for receptor home range |
| BW | = Body weight of the receptor, wet weight |
| $EDD_{substrate}$ | = Dose of COPEC obtained from substrate (mg COPEC/kg receptor body weight-day) |
| $IR_{substrate}$ | = Incidental Ingestion rate of substrate (kg substrate ingested per day, dry weight) |
| $C_{substrate}$ | = COPEC concentration in substrate (mg COPEC/kg substrate, dry weight) |

**Table 11**
**Refined Terrestrial Dose Rate Model Output (Southern AOC)**
**Ecological Risk Assessment**
**Construction Debris Landfill, Wallops Island, Virginia**

**Notes:**
bw/d = body weight per day; COPEC = Chemical of Potential Ecological Concern; EPC = Exposure Point Concentration; Invert. = Invertebrates;
kg = kilogram; LOAEL = Lowest Observable Adverse Effect Level; mg = milligram; N/A = Not Available; NOAEL = No Observable Adverse Effect Level;
TRV = toxicity reference value; -- = not evaluated

(a) Dietary dose calculated as:

$$EDD_{diet} = \frac{IR_{diet} \times \sum(B[S]AF \times C_{soil} \times DF_i) \times AUF}{BW}$$

(b) Substrate dose calculated as:

$$EDD_{substrate} = \frac{IR_{substrate} \times C_{substrate} \times AUF}{BW}$$

(c) Total dose calculated as:

$$EDD_{total} = EDD_{diet} + EDD_{substrate}$$

**Where:**

| | |
|---|---|
| $EDD_{diet}$ | = Dose of COPEC obtained from the diet (mg COPEC/kg receptor body weight-day) |
| $IR_{diet}$ | = Ingestion rate of food (kg food ingested per day, dry weight) |
| B(S)AF | = Bioaccumulation factor (BAF) or biota-sediment accumulation factor (BSAF), specific to prey type and COPEC (kg substrate/kg food, dry weight) |
| $C_{soil}$ | = COPEC concentration in soil (mg COPEC/kg soil, dry weight) |
| $DF_i$ | = Dietary fraction of food item *i* |
| AUF | = Area use factor accounts for receptor home range |
| BW | = Body weight of the receptor, wet weight |
| $EDD_{substrate}$ | = Dose of COPEC obtained from substrate (mg COPEC/kg receptor body weight-day) |
| $IR_{substrate}$ | = Incidental Ingestion rate of substrate (kg substrate ingested per day, dry weight) |
| $C_{substrate}$ | = COPEC concentration in substrate (mg COPEC/kg substrate, dry weight) |

**Notes:**
bw/d = body weight per day; COPEC = Chemical of Potential Ecological Concern; EPC = Exposure Point Concentration; Invert. = Invertebrates;
kg = kilogram; LOAEL = Lowest Observable Adverse Effect Level; mg = milligram; N/A = Not Available; NOAEL = No Observable Adverse Effect Level;
TRV = toxicity reference value; -- = not evaluated

(a) Dietary dose calculated as:

$$EDD_{diet} = \frac{IR_{diet} \times \sum(B[S]AF \times C_{soil} \times DF_i) \times AUF}{BW}$$

(b) Substrate dose calculated as:

$$EDD_{substrate} = \frac{IR_{substrate} \times C_{substrate} \times AUF}{BW}$$

(c) Total dose calculated as:

$$EDD_{total} = EDD_{diet} + EDD_{substrate}$$

**Where:**

$EDD_{diet}$ = Dose of COPEC obtained from the diet (mg COPEC/kg receptor body weight-day)
$IR_{diet}$ = Ingestion rate of food (kg food ingested per day, dry weight)
B(S)AF = Bioaccumulation factor (BAF) or biota-sediment accumulation factor (BSAF), specific to prey type and COPEC (kg substrate/kg food, dry weight)
$C_{soil}$ = COPEC concentration in soil (mg COPEC/kg soil, dry weight)
$DF_i$ = Dietary fraction of food item *i*
AUF = Area use factor accounts for receptor home range
BW = Body weight of the receptor, wet weight
$EDD_{substrate}$ = Dose of COPEC obtained from substrate (mg COPEC/kg receptor body weight-day)
$IR_{substrate}$ = Incidental Ingestion rate of substrate (kg substrate ingested per day, dry weight)
$C_{substrate}$ = COPEC concentration in substrate (mg COPEC/kg substrate, dry weight)
