# APOLLO 12 LUNAR-SAMPLE INFORMATION 

By Jeffrey Warner, Compiler<br>Manned Spacecraft Center

SUMMARY

The second manned lunar landing occurred on November 19, 1969, when the Apollo 12 lunar module touched down on the Ocean of Storms. The scientific data obtained between November 25, 1969, and January 30, 1970, during the preliminary examination of the lunar samples returned from the Apollo 12 mission are presented in this report. Descriptions of the sample-collecting tools and techniques and of the contingency, selected, documented, and tote-bag samples are given. A preliminary search was conducted to determine the localities and orientations of the samples on the lunar surface; however, much work remains to be done to complete this task. Mineralogical/petrological, chemical, gamma-ray spectrometry, noble gas, total carbon, organic mass-spectrometry, and organic-monitor analyses were performed on the lunar samples, and the results are given and discussed.

Photographs and detailed descriptions of the samples, plots and descriptions of the samples and controls that were subjected to organic analysis, and details of the organic-contamination monitors and controls are presented. Photographic documentation is presented in (1) a log of all photographs taken both on the lunar surface and in the Lunar Receiving Laboratory, (2) an index of photographs by sample number and an index of samples by photograph number, and (3) a cross-reference of samples with the lunar-surface collection locations, photographs, and chronological sequence.

The major findings of the preliminary examination of the Apollo 12 lunar samples can be contrasted with the major findings of the samples from the first manned lunar landing (the Apollo 11 mission which landed on the Sea of Tranquility on July 20, 1969) as follows.

1. Although still old by terrestrial standards, the Apollo 12 rocks are approximately 1 billion years younger than the Apollo 11 rocks.
2. Whereas microbreccias comprised approximately one-half of the Apollo 11 samples, the Apollo 12 suite contained only two breccias in the 45 rocks returned.
3. The regolith at the Apollo 12 site was approximately one-half as thick as that at the Apollo 11 site.
4. Considerably less solax-wind material was found in the Apollo 12 fines than in the Apollo 11 fines.
5. The crystalline rocks in the Apollo 12 collection, in contrast to those from the Apollo 11 mission, displayed a wide range in both modal mineralogy and primary texture.
6. Chemically, the "nonearthy" character (high refractory and low volatileelement concentrations) of the Apollo 11 samples was evident in the Apollo 12 samples but to a lesser degree.
7. The chemical composition of the Apollo 12 fines equaled that of the breccias but did not equal that of the crystalline rocks; this was not observed in the Apollo 11 samples.

Much of the sample information given in this document was collected under less than optimum conditions and in a short time; therefore, all data should be considered preliminary.

## INTRODUCTION

This document is a rapid compilation of the scientific data about the lunar samples returned by the Apollo 12 crew. The purpose of this report is to provide the lunar-sample Principal Investigators and other scientists with general information concerning the total lunar samples returned and with specific information about individual samples that were distributed for detailed analyses. It is hoped that this document will aid the Principal Investigators in putting the samples they receive into the larger context of lunar science. This report is a companion document to the NASA Apollo 12 Preliminary Science Report.

The following information is contained in the appendixes: (1) Mineralogical/ petrological descriptions of the samples (appendix A); (2) results of the total carbon and organic analyses (appendix $B$ ); (3) the organic monitors (appendix C); (4) a comprehensive photographic index (appendix D); and (5) major updates to July 31, 1970 (appendix E).

The data contained in this report were collected in the Lunar Receiving Laboratory (LRL) at the Manned Spacecraft Center (MSC) by the linnar sample Preliminary Examination Team (PET) and the Lunar Field Geology Experiment Team during and immediately after the Apollo 12 mission. Team members are as follows.

## CHEMICAL ANALYSIS AND X-RAY GROUP:

J. H. Allen, Brown and RootNorthrop (BRN)
A. D. Bennett, BRN
J. B. Dorsey, BRN
P. H. Johnson, BRN
J. R. Martin, BRN
W. B. Nance, BRN

D. H. Smith, UCB

SOIL MECHANICS GROUP:
W. D. Carrier, MSC
N. C. Costes, Marshall Space Flight Center
J. K. Mitchell, MIT
R. F. Scott, California Institute of Technology

TOTAL CARBON ANALYSIS GROUP:
E. K. Gibson, MSC
C. F. Lewis, Arizona State
University (ASU)

The author would like to ackrowledge the special help in editing this document given by Daniel Anderson, Robin Brett, and Donald Flory. Also, the author wishes to thank Beverly Atkinson without whose efforts this report would not have been possible.

$$
\text { THE APOLLO } 12 \text { MISSION }
$$

The primary purpose of the Apollo 12 mission was to demonstrate a pinpoint landing capability on the lunar surface. The crewmembers were Charles Conrad, Jr., Commander (CDR), Richard Gordon, Command Module Pilot (CMP), and Alan Bean, Lunar Module Pilot (LMP).

The space vehicle was launched from Kennedy Space Center, Florida, at 11: 22 a.m. e.s.t. on November 14, 1969. The lunar module (LM) landed in the Ocean of Storms (fig. 1) at 110: 32: 35 ground-elapsed time, approximately 200 meters from the Surveyor III spacecraft (fig. 1(d)). The landing coordinates were $2.45^{\circ} \mathrm{S}$ latitude and $23.34^{\circ} \mathrm{W}$ longitude.

(a) Broad view (NASA-S-69-39524).

(b) General.

Figure 1.- Apollo 12 lunar-landing site.

Figure 1.- Concluded.

## Extravehicular Activity

The extravehicular activity (EVA) on the lunar surface was divided into two 4 -hour traverses separated by an 8 -hour eat/rest period. The length of each EVA was dictated by the capabilities; of the life-support system. Four types of samples (contingency, selected, documented, and tote bag) were collected from the lunar surface and returned to the LRL. The sample return is listed in table I.

TABLE I. - LUNAR-SAMPLE RETURN

| Type of sample <br> (a) | Weight, g |
| :---: | :---: |
| Contingency sample |  |

${ }^{a}$ Fines are less than 1 centimeter, chips are between 1 and 4 centimeters, and rocks are larger than 4 centimeters.

In addition to collecting samples, the main scientific tasks to be accomplished during the extravehicular activities were (1) photographing rocks, the lunar surface, and the moonscape; (2) deploying the Apollo lunar-surface experiments package (ALSEP) during the first EVA; (3) collecting parts from the Surveyor III spacecraft during the second EVA; and (4) deploying and retrieving the solar-wind foil. The ALSEP contained a central-power communication station and five experiment units: the passive seismometer, the cold-cathode ion gage, the suprathermal ion detector, the solar-wind spectrometer, and the magnetometer.

## Sample-Collecting Tools and Techniques

To obtain samples of the lunar surface, the Apollo 12 crew used the samplecollecting tools and techniques described in the following paragraphs. The tools were designed of material that was durable enough to accomplish the tasks yet light enough to conform to the weight and space limitations of the LM stowage area. The limitations imposed on the movements of a crewman while wearing a pressurized space suit also had to be considered; therefore, the tools were designed with quick-disconnect fittings to enable the crewman to attach or detach components with minimum difficulty. Knurled or roughened areas were provided on many tools to improve the crewman's grip, and an extension handle was provided to lengthen the crewman's reach. Prime consideration was given to the selection of the metals and lubricants used in the construction of the tools to avoid elements and isotopes (such as lead ( Pb ), strontium ( Sr ), et cetera) that might contribute to serious geochemical contamination of the lunar material.

The contingency-sample container (fig. 2(a)) consisted of a small Teflon bag and a jointed aluminum handle that was approximately 84.5 centimeters long in the fixed extended position. The Teflon bag measured 5.2 by 12.7 by 17.8 centimeters. The contingency-sample container was used to obtain a lunar sample during the early stages of the first EVA.

The two Apollo lunar-sample-return containers (ALSRC) (fig. 2(b)) were portable, sealable aluminum containers. Each ALSRC weighed approximately 6.8 kilograms, measured 20.3 by 26.7 by 44.5 centimeters, and had a capacity of 0.023 cubic meter. Before the lunar landing, the containers housed the core tubes and other related equipment. On the lunar surface, the astronauts opened, filled, and closed the containers. The three seals on the hinged lids (one of indium (In) and two of Viton) preserved the samples in a vacuum environment during transportation back to the LRL.

Figure 2.- Sample-collecting equipment.

The hammer (fig. 2(c)) was made of tool steel suitable for impact use. The head was coated with vacuum-deposited aluminum to minimize solar heating. The handle was offset.slightly so that the crewman could strike a direct blow despite the encumbrance of the pressurized space suit. One end of the hammerhead was shaped for use as a pick or chisel; with the extension handle attached, it could have been used as a hoe for trenching or digging. The hammer also could have been used for driving the core tubes into the subsurface by striking the end of the extension handle.

The tongs (fig. 2(d)) were constructed of anodized aluminum and were used to retrieve samples of pebble size and larger. This tool consisted of a set of opposed spring-loaded fingers attached to a 66 -centimeter-long handle. The tongs were operated by squeezing the handles to actuate the cable that opened the fingers.

Figure 2. - Continued.
The large scoop (fig. 2(e)) was constructed of anodized aluminum. The length of the scoop and handle was 39.4 centimeters and could have been extended an additional 58.4 centimeters by use of the extension handle. The large scoop was used during the lunar EVA to collect the selected sample.

The small scoop (fig. 2(f)) was 29.8 centimeters in length. The pan of the scoop had a flat bottom that was flanged on both sides and a partial cover on the top to prevent loss of contents. It was used to retrieve sand, dust, or other lunar material too small for the tongs. The small scoop was made of anodized aluminum with a steelalloy inset on the front edge that was suitable for cutting cohesive material. The handle had a quick-disconnect mount for attaching the extension handle.

Figure 2. - Continued.

The core tubes (fig. 2(g)) were constructed of anodized aluminum and were used to obtain samples from the lunar surface in such a manner that the near-surface stratigraphy was preserved. The core tubes were 41.3 centimeters long and could be attached to the extension handle. Four tubes were used on the Apollo 12 mission.

The extension handle (fig. 2(h)) increased the crewman's reach by adding 58.4 centimeters of handle length to various tools. The lower end of the extension handle had a quick-disconnect mount and lock for tool aitachment. The upper end was fitted with a sliding T -handle to facilitate torquing operations.

Figure 2. - Concluded.

The gnomon was a stadia rod mounted on a tripod and was constructed so that the rod would right itself and point vertically when the legs were put down on the lunar surface. The gnomon was an indicator of the gravitational vector and provided accurate vertical reference and calibrated length for determining the size and position of objects in near-field photographs. The shadow cast by the staff indicated the solar position. The gnomon had a finish painted in shades of gray ranging in reflectivity from 5 to 35 percent in 5 -percent increments and a color scale of blue, orange, and green. The scales were provided as a means of accurately determining colors in color photographs. The rod was 45.7 centimeters long, and the tripod base folded for compact stowage in the modularized equipment-stowage assembly.

The individual sample bags also were known as the documented sample bags or as the 'Dixie cups." The bags were made of Teflon and had an aluminum crimping ring. Each bag could hold approximately one-third liter.

## Lunar Samples

The Apollo 12 sample return and inventory are listed in tables I and II. The mass distribution of the samples is shown in table III.

TABLE II. - LUNAR-SAMPLE INVENTORY

| Sample number | Mass, g | Type code <br> (a) | Remarks |
| :---: | :---: | :---: | :---: |
| Selected samples ${ }^{\text {b }}$ |  |  |  |
| 12001 | 2216.0 | D | Less than $1-\mathrm{cm}$ vacuum fines |
| 12002 | 1529.5 | B | Olivine dolerite ${ }^{\text {c }}$ - vacuum ${ }^{\text {d }}$ |
| 12003 | 300.0 | D | Fines and chips |
| 12004 | 585.0 | A | Olivine basalt - vacuum |
| 12005 | 482.0 | A | Olivine basalt - vacuum |
| 12006 | 206.4 | AB | Olivine basalt with radiating feldspar laths |
| 12007 | 65.2 | A | Basalt |
| 12008 | 58.4 | AB | Cumulate (ilmenite) |
| 12009 | 468.2 | A | Porphyritic olivine (feldspar) basalt, large depression - vacuum |
| 12010 | 360.0 | A | Basalt - vacuum |
| 12011 | 193.0 | A | Olivine basalt - vacuum |
| 12012 | 176.2 | AB | Olivine basalt - vacuum |
| 12013 | 82.3 | A | Igneous breccia - vacuum |
| 12014 | 159.4 | B | Olivine dolerite - vacuum |

${ }^{\mathrm{a}}$ Type A, fine-grained vesicular crystalline igneous rocks; type $B$, mediumgrained vuggy crystalline igneous rocks; type C, breccias; type D, fines; and type E, chips.
$\mathrm{b}_{\text {The }}$ S-ALSRC contained 40 to 60 microns of pressure when returned to the LRL.
${ }^{c}$ Dolerite is a rock of basaltic composition with an intermediate crystal size.
d Samples 12002 to 12022 labeled "vacuum" were exposed to 1 atmosphere of nitrogen ( N ) for at least 2 hours.

${ }^{\mathrm{a}}$ Lunar fines or fines and chips.

Contingency sample. - The contingency sample (table I) was collected early during the first EVA to assure that some lunar material would be returned in the event that the extravehicular activities were aborted. The CDR collected the contingency sample 10 meters southwest of the LM. Approximately five scoops were made to collect the 2 kilograms (including four rock $s$ ) of material.

Selected samples. - The selected samples (table I) replaced the ''bulk'" samples of Apollo 11 and were collected northwest of the LM (up to 300 meters away) during the last part of the first EVA. Seventeen rocks were collected with the tongs and placed in a large Teflon bag. Three large rocks (about 2 kilograms each) were collected with the tongs and placed in a second large Teflon bag, which then was filled with lunar fines using the scoop. One core tube was driven. The two Teflon bags and the core tube were sealed on the lunar surface in the ALSRC containing the selected samples (S-ALSRC).

The pressure in the S-ALSRC at the time of probing was 40 to 60 microns. Nitrogen ( N ) and oxygen ( O ) were the major gases present, with small amounts of helium (He), argon (Ar), and carbon dioxide ( $\mathrm{CO}_{2}$ ). The N/Ar ratio was essentially that of air. The $\mathrm{O} / \mathrm{N}$ ratio appeared to be greater than air and possibly signified S-ALSRC leakage within the Apollo spacecraft. Water was quite low and may have been partially absorbed by the lunar material. No organic components above the background level were observed.

Documented samples. - The documented samples (table I) were collected during the second EVA while the astronauts were on their 1.5 -kilometer geological traverse (fig. 3). The samples were documented by photography. During the traverse, the astronauts filled 13 individual sample bags with 11 rocks and seven lunar-fines samples. These samples were collected with a scoop and the tongs. Ten additional rocks were collected with the tongs. Two core tubes were driven, one of which was a double tube. The two special samples for the gas-analysis sample container (GASC) and the lunar-environment sample container (LESC), which were designed to be sealed individually, were collected. All of these samples except the four largest were sealed on the lunar surface in the ALSRC containing the documented samples (D-ALSRC).

The pressure in the D-ALSRC at the time of probing was not measured; however, all indications are that the sample box was at a significant fraction of atmospheric pressure. The $\mathrm{N}, \mathrm{O}$, and Ar gases were in essentially atmospheric proportions. Compared to N, O was lower and water was higher in the D-ALSRC than in the S-ALSRC. Some amount of excess He was evident. No organics or Freon compounds were observed.

Figure 3.- Extravehicular traverse map showing sample localities.

Tote-bag samples. - A tote-bag sample was not collected on Apollo 11. The Apollo 12 tote-bag samples (table I) were the four rocks that were not sealed in the D-ALSRC. The rocks were placed in a large Teflon bag.

All four sample containers were taken into the LM, bagged, and, after rendezvous, transferred to the command module (CM). The S-ALSRC and the D-ALSRC were returned by air to the LRL on November 25, 1969. The contingency and tote-bag sample containers were returned to the LRL in the Mobile Quarantine Facility on November 30, 1969.

## LUNAR RECEIVING LABORATORY OPERATIONS

The configuration and operations of the biological barriers in the LRL remained essentially the same as for Apoll.o 11 (ref. 1). The selected samples were opened and studied in vacuum (generally about $10^{-6}$ torr). The documented, contingency, and tote-bag samples and the core tubes were opened and studied in dry -nitrogen glove cabinets. Approximately 50 grams of core-tube material and 450 grams of fines and rock chips from the documented and selected samples were designated for biological testing. The compositions of the early and regular biological test samples are shown in table IV.

## Geological Setting

The Apollo 12 LM landed on the northwest rim of the 200 -meter-diameter Surveyor Crater (the crater in which Surveyor III landed on April 20, 1967) at $2.45^{\circ} \mathrm{S}$ latitude and $23.34^{\circ} \mathrm{W}$ longitude, about 120 kilometers southeast of the crater Lansberg. The site is on a broad ray of the crater Copernicus.

The landing site is characterized by a distinctive cluster of craters ranging in diameter from 50 to 400 meters (fig. 3). The informal names given to these craters for use during the mission also are used in this report. The EVA traverses generally were made on or near the rims of these named craters and on deposits of ejecta from them.

The lunar surface at the Apollo 12 landing site is underlain by fragmental material (the lunar regolith) which ranges from particles too small to be seen with the naked eye to blocks several meters across. Along many parts of the traverse made during the second EVA, the astronauts found fine-grained material of relatively high albedo which, at some places, was at the surface. This light-gray material possibly may be part of a discontinuous deposit observed through the telescope as a ray of the crater Copernicus.

The darker regolith material that generally overlies the light-gray material is only a few centimeters thick in some places; however, it is probably much thicker on the rims of some craters. The darker material varies from place to place in the size, shape, and abundance of the constituent particles and in the presence or absence of patterned ground. Most of the local differences are probably the result of local cratering events.

Beads and small irregularly shaped fragments of glass are abundant both on and within the regolith; glass also is spattered on some of the rocks at the surface and is found in many shallow craters.

The larger craters at the landing site probably differ widely in age. The age sequence from oldest to youngest is interpreted as follows.

1. ''Middle Crescent' (''1000 foot' $)$ Crater
2. ''Surveyor' ${ }^{\prime}$ and ' 'Head'' Craters
3. ''Bench' Crater
4. 'Sharp, " "Halo, " and ''Block'" Craters

When looking down into Middle Crescent Crater, the astronauts noticed huge blocks on the wall which probably originated from the local bedrock. The large rock fragments in this crater probably have been exposed the longest and represent the deepest layers excavated at the Apollo 12 landing site.

Both rounded and angular blocks litter the surface of the rims of Head and Bench Craters. Some rocks appeared to be coarse grained to the astronauts; the crystals were clearly visible. Many rocks on the rim of Bench Crater were reported to be spattered with glass.

Samples were collected from three small, very fresh, blocky-rimmed craters that apparently penetrate through the regolith into the underlying materials. The three craters are Sharp Crater (approximately 14 meters across and 3 meters deep), Block Crater (approximately 13 meters across and 3 meters deep), and an unnamed crater ( 2 meters across and 0.5 meter deep) that lies on the south rim of the Surveyor Crater just north of Halo Crater.

Sharp Crater has a 66.7-centimeter-high rim that is composed of material with a high albedo. The material has been splashed radially around the crater and is softer than the normal regolith. A core tube driven into the rim of the crater penetrated the ejecta without difficulty. Samples collected at this location may show the youngest exposure ages. Sharp Crater appears to have just penetrated the regolith; a terrace on the floor probably is controlled by the subregolith bedrock.

At Block Crater, located high on the north wall of Surveyor Crater, almost all the ejected blocks are sharply angular, which indicates that the crater is very young. Many blocks clearly show lines of vesicles that are similar in appearance to vesicular lavas on earth. The blocks probably are derived from an older coarse blocky ejecta deposit underlying the rim of the Surveyor Crater.

The 4 -meter blocky crater on the crest of the southern rim of the Surveyor Crater may have been excavated in an old rim deposit at a depth of less than 0.5 meter. The regolith at this location may be very thin.

One notable difference between the rocks from the Apollo 12 site and those from the Apollo 11 site is that the Apollo 12 rocks are predominantly crystalline, whereas approximately half of the Apollo 11 rocks were crystalline and half were microbreccia. The difference probably is due to the fact that the Apollo 12 rocks were collected primarily on or near crater rims. The regolith on the crater rims is thin or only weakly developed, and many of the rocks are probably from craters that have been excavated in bedrock well below the regolith. The Apollo 11 site, in contrast, was located on a thick mature regolith where many of the observed rock fragments were produced by induration of regolith material and ejected from craters too shallow to excavate bedrock.

## Lunar-Soil Mechanics

The properties of the Apollo 12 regolith may be presented best by a comparison with the properties of the Apollo 11 soil. The two sites were similar in the following respects.

1. Lunar module touchdown: Similar penetrations were observed under similar landing conditions, indicating that the soil-bearing capacities at the two sites are of the same order of magnitude.
2. Astronaut boot prints: The depth of the boot prints of the Apollo 12 astronauts was of the same order observed for the Apollo 11 astronauts; that is, less than 1 centimeter in the immediate vicinity of the LM and in the harder soil areas and up to several centimeters in the soft-soil areas, especially in the rims of small and relatively young craters.
3. Color, grain size, adhesion, and cohesion: Most of the Apollo 12 soil samples are visually identical to the Apollo 11 soil samples. The similarities of these properties are discussed further in the section on fines.

The two sites were significantly different in the following respects.

1. Lunar-surface rocket-exhaust erosion: The Apollo 12 astronauts experienced greater loss of visibility because of soil erosion during the LM landing than did the Apollo 11 astronauts. Further analysis is necessary to determine whether the loss of visibility was caused by different soil conditions, by a different descent profile, or by both.
2. Core-tube penetration and trenching: The Apollo 12 astronauts were able to drive the core tubes to the full depth (approximately 70 centimeters for the double core tube); whereas the Apollo 11 astronauts were able to drive the tubes only about 15 centimeters. A different bit design was used on the Apollo 12 core tubes which probably helped in driving them. The Apollo 12 trenches were dug to a depth of 20 centimeters, and the astronauts reported that the trenches could have been extended to a considerably greater depth without difficulty. The Apollo 11 astronauts could dig only about 10 centimeters.
3. Color and grain size: The differences in the color and grain size of the lunar soil are discussed in more detail in the section on fines.

A preliminary comparison of the photographs taken by the Apollo 12 astronauts at the Surveyor III site with the photographs relayed to earth by Surveyor III in April 1967 suggests that the lunar surface has undergone little change in the past $2-1 / 2$ years. The trenches excavated by the Surveyor III soil-mechanics surface sampler and the waffle pattern of the Surveyor III footpad imprint appear much the same in the Apollo 12 photographs as when they were formed. The astronauts reported that Surveyor III was coated with a thin layer of dust.

## SAMPLE LOCATIONS

A preliminary search was made to determine the localities of the contingency sample, the selected samples collected during the first EVA, and the documented and tote-bag samples collected during the second EVA. The contingency sample was well documented with Hasselblad photographs taken by the CDR and with 16-millimeter time-sequence photographs taken from the right-hand window of the LM. The scoop marks can be seen clearly in these photographs. Two rock fragments collected as part of the contingency sample have been tentatively identified in the photographs.

Each selected-sample collection site generally was photographed once. A very preliminary search has been undertaken to identify the selected samples in these photographs; however, much work remains to be done to complete this task. Three of approximately 20 sample sites have been tentatively identified.

The collection of samples during the second EVA was planned to be documented by a series of four photographs: three (including a stereopair) to be taken before collection and one to be taken after collection to record the site from which the sample had been removed. This photographic plan was followed in only a few cases, and the documentary record of the samples returned from the second EVA is not sufficient for identification of all the samples. Thus far, eight individual rocks have been identified in the Hasselblad photographs taken during the second EVA. Four samples have been tentatively identified, and the locality of another four samples is fairly well known. The locality of approximately 10 samples is not known.

## SAMPLE IDENTIFICATION AND ORIENTATION

The identification and orientation of the samples were based on the comparison of the photographs taken in the LRL with the photographs taken on the lunar surface before and after the samples were collected. Two sample identifications (samples 12052 and 12054) were verified in the LRL by reorienting the samples under a photographic lamp to duplicate the characteristic shadows shown in the EVA photographs. More samples will be verified this way.

## Contingency Sample

The contingency sample was collected in full view of the sequence camera on and near the southeast rim of a 6-meter-diameter crater approximately 15 meters northwest of the LM (figs. 3 and 4 (a)). The sample was collected in six distinct scoop motions and consisted of a total of 1.9 kilograms of selected rock fragments (three of which were more than 5 centimeters in the longest dimension), fine-grained material, and at least one glass bead. The locations of the areas that were scooped (fig. 4(a)) were identified in the sequence.-camera photographs taken from the LM windows before the first EVA. All six sample scoop marks are documented on surface photographs AS12-46-6719 to AS12-46-6723.

The first and sixth scoops included rock fragments that were visible from the LM windows before sampling; these fragments may be samples 12075 and 12073, respectively. These samples, which are shown in Hasselblad photograph AS12-48-7031 (fig. 4(a)), were collected from a group of small rocks alined roughly northeast/ southwest between two small craters located 15 meters northwest of the LM. Most of the rocks appear to have fillets banked against them. The surface near the line of rocks has numerous small craters that may have contributed to the fillets; however, it has not been determined whether any of the rocks were the projectiles that caused the craters. The suggested selenographic orientations of samples 12073 and 12075 are shown in figures 4 (b) and 4 (c).

(a) Contingency-sample collection area showing the sequence and direction of the six scoops and the positions of the samples before collection (AS12-48-7031).

(b) Suggested selenographic orientation of sample 12073 (NASA-S-69-61060).

(c) Suggested selenographic orientation of sample 12075 (NASA-S-69-61490).

Figure 4. - Concluded.

## Selected Samples

The identification and orientation of the presampling position of three selected sample rocks (samples 12004, 12021, and 12022) have been tentatively determined. Three other rocks (samples 12006, 12008, and 12014) have been tentatively identified, but the orientation in the surface photographs has not yet been determined. The areal distribution of the selected samples (table V) was determined from the study of surface photographs and from the verbal transcript of the EVA communications. Specific sample numbers are given for several other rocks where identification was aided by the astronaut's description.

TABLE V. - AREAL DISTRIBUTION OF SELECTED SAMPLES

| Location | Type of sample | Sample number |
| :---: | :---: | :---: |
| Small mound north of ALSEP | Rocks (2) | $12017(?)$ |
| Large mound south of ALSEP | Rocks (5) | $12008(?)$ |
|  |  | $12021(?)$ |
| On or near rim of Middle Crescent | Rocks (7) | $12022(?)$ |
| Crater |  | $12004(?)$ |
|  |  | $12006(?)$ |
|  |  | $12014(?)$ |
| Intercrater area near ALSEP and |  | $12016(?)$ |
| northwest of LM | Rocks (6) | Fines with |

Sample 12004. - Sample 12004 has been tentatively identified in Hasselblad photograph $\overline{\text { ASS12-47-6936 (fig. 5(a)), which was taken at the photographic panoramic site }}$

(a) Sample 12004 before collection (AS12-47-6936).

Figure 5. - Extravehicular activity photographs and orientation diagrams of Apollo 12 selected samples.
near the rim of Middle Crescent Crater. The rock appears in the photograph as an isolated rock fragment that is standing on end approximately half embedded in the lunar regolith. The specimen was correlated with NASA photograph S-69-62023. The suggested selenographic orientation of sample 12004 is shown in figure 5(b).

(b) Suggested selenographic orientation of sample 12004 (NASA-S-69-62023).

Figure 5.- Continued.

Sample 12021. - Sample 12021 has been tentatively identified in Hasselblad photograph AS12-47-6932 (fig. 5(c)), which was taken from the area near the eastern base of the large mound located between Head Crater and the ALSEP site. The rock specimen was correlated with NASA photograph S-69-61986. A model of sample 12021 under simulated lunar conditions is shown in figure 5(d). The suggested selenographic orientation is shown in figure 5(e).

(c) Sample 12021 before collection (AS12-47-6932).

(d) P hotograph of model of sample 12021 under simulated lunar conditions.

(e) Suggested selenographic orientation of sample 12021
(NASA-S-69-61985).
Figure 5. - Continued.

Sample 12022. - Sample 12022 has been tentatively identified as the rock shown just beneath the tongs in Hasselblad photograph AS12-47-6933 (fig. 5(f)). If correctly identified, the sample is a piece of embedded crystalline rock that was collected approximately 66.7 centimeters from the top of the large mound north of Head Crater. The rock may not be representative of the bulk of the mound material, which appears to be composed predominantly of aggregates of fine particles. The mound may be a large clot of regolith material that was ejected from a nearby crater. The specimen was correlated with NASA photograph S-69-61999 on the basis of the diagnostic triangular shape and the chipped depression at the small end of the rock. The suggested selenographic orientation of sample 12022 is shown in figure $5(\mathrm{~g})$.

(f) Sample 12022 before collection
(AS12-47-6933).

(g) Suggested selenographic orientation of sample 12022 (NASA-S-69-61999).

Figure 5. - Concluded.

## Documented Samples

The areal distribution of all samples collected during the documented sample traverse of the second EVA is shown in table VI.

TABLE VI.- AREAL DISTRIBUTION OF DOCUMENTED SAMPLES

| Location | Type of sample | Sample number | Container |

Sample 12030. - Sample 12030 consists of the group of fragments that are shown in Hasselblad photographs AS12-48-7043 and AS12-48-7044. The sample was collected by the LMP from a crater (approximately 1 meter in diameter) located on the outer northeast flank of the rim of Head Crater. The LMP passed this small crater as he traversed from the LM to join the CDR on the north rim of Head Crater; the precise position has not been determined accurately. The sample includes part of the fragmental lining of the 1 -meter crater. Most of the lining appears to consist of weakly coherent aggregates of regolith material and resembles the lining observed in experimentally produced secondary craters. The LMP reported the collection from the crater of several small fragments that were partly glass covered. Other fragments that he attempted to pick up with the tongs were soft and crumbled. The fragments with the glass coatings may have been embedded in the regolith at this site or may have been part of the projectile that formed the 1 -meter crater.

Sample 12031. - Sample 12031 has been identified in Hasselblad photograph AS12-49-7189, AS12-49-7190, and AS12-48-7048 (fig. 6(a)), taken before collection, and in Hasselblad photograph AS12-48-7050, taken after collection. The identification of this sample is precise because photographs were taken both before and after collection and because the sample was put into a prenumbered bag (3-D) and identified when it was picked up. The sample was collected from a small cluster of rocks about 2 meters southeast of the trench that was dug in the northwest rim of Head Crater and was almost half buried in the fine-grained regolith. There is the suggestion of a small fillet banked on the north and northeast sides of the rock. Other

(a) Sample 12031 before collection (AS12-48-7048).

Figure 6. - Fixtravehicular activity photographs and orientation diagrams of Apollo 12 documented samples.
nearby rocks have fillets with predominantly similar orientations, indicating a possible source of material to the north or northeast. The selenographic orientation of sample 12031 is shown in figure 6(b).

(b) Suggested selenographic orientation of sample 12031.

Figure 6. - Continued.

Sample 12032. - Sample 12032 includes soil and small rock fragments. The sample has not been identified in Hasselblad photographs, but the astronauts indicated that the sample was taken from the north rim of Bench Crater. The astronauts noted lightgray material just below the surface at this locality that was similar to the material which they had observed at the Head Crater trench site.

Sample 12033. - Sample 12033 is a soil sample that was collected approximately 15 centimeters below the surface in a trench dug on the northwest rim of Head Crater near the site of sample 12031. The material that was sampled from the trench was noticeably lighter gray than the surface of the regolith at this site or than the material noticed by the astronauts in the vicinity of the LM and the ALSEP deployment area. The trench, at several stages of excavation, is portrayed clearly in Hasselblad photographs AS12-49-7191 to AS12-49-7196 (taken by the CDR), and AS12-48-7049, AS12-48-7051, and AS12-48-7052 (taken by the LMP).

Sample 12034. - Sample 12034 is a specimen of microbreccia that was dug from the bottom of the trench on the northwest side of Head Crater where soil sample 12033 was taken. After excavation, the specimen was placed on the surface near the trench and photographed by the CDR (Hasselblad photographs AS12-49-7195 and AS12-49-7196). The site where the specimen was placed and later removed is shown in Hasselblad photographs AS12-48-7051 and AS12-48-7052 (taken by the LMP). When unpacked in the laboratory, the specimen was coated with the light-gray fine-grained regolith material in which it was buried in the trench.

Sample 12035. - Sample 12035 consists of six principal fragments that were broken from a fractured almost-buried rock on the northwest rim of Bench Crater. The fractured rock is shown clearly in Hasselblad photographs AS12-49-7336 and AS12-49-7337 (taken by the CDR) and AS12-48-7034 (taken by the LMP). The rock appears to have impacted the surface at this site relatively recently and to have broken on impact. The impact of the rock produced a small crater that is much more freshly formed than other craters on the rim of Bench Crater and is not, therefore, related directly to Bench Crater. Small pieces broken from the rock in the LRL were found to be weak and friable; the original rock was apparently very weak and may have been partly crushed by shock during ejection from some moderately distant crater. It does not appear possible to determine the field orientation of any of the individual fragments returned or to relate them to the individual parts of the original rock in the lunar-surface photograph.

Sample 12036. - Sample 12036 is an individual rock specimen that was collected near the site of sample 12035 on the northwest rim of Bench Crater. On the basis of their field observations, the astronauts believe this rock fragment at some time may have been broken from the fractured rock from which the pieces of sample 12035 were collected. Sample 12036 has not yet been identified in the photographs but may be recognized after further study.

Sample 12037. - Sample 12037 is a soil sample that was collected and placed in the bag with the rock fragment of sample 12036.

Sample 12038. - Sample 12038 is a rock fragment that was collected from the west rim of Bench Crater. The specimen may be shown in Hasselblad photographs AS12-49-7240 and AS12-49-7241 (taken by the CDR) but has not yet been
identified. At this locality, abundant coarse rock fragments occur that probably were excavated from beneath the regolith and ejected from Bench Crater.

Samples 12039 and 12040. - Samples 12039 and 12040 are rock specimens collected from the west rim of Bench Crater near the site of sample 12038. These rocks may be shown in Hasselblad photographs AS12-49-7240 and AS12-49-7241 (taken by the CDR before sample collection) but have not yet been identified. The specimens were picked up from the surface and then laid down near the tool carrier and photographed by the CDR (Hasselblad photographs AS12-49-7242 and AS12-49-7243) before they were placed in the sample bag. The astronauts tried to be selective in choosing rocks that they thought most likely represented material ejected from the bottom of Bench Crater. Samples 12038, 12039, and 12040 represent the rocks brought back from this selection.

Sample 12041. - Sample 12041 is a soil sample collected a short distance east of Bench Crater on the traverse between Sharp Crater and Halo Crater. The material consists mostly of fine particles but includes a 6.4-millimeter-diameter glass sphere. The locality was not documented by photographs.

Sample 12042. - Sample 12042 is a soil sample taken on the outer flank of the Surveyor Crater rim, about 50 meters northwest of Halo Crater. The general site from which the sample was taken is shown in Hasselblad photographs AS12-49-7282 to AS12-49-7284 (taken by the CDR) and AS12-48-7072 to AS12-48-7076 (taken by the LMP). This area was noted by the astronauts as being different in texture from the other parts of the lunar surface over which they had walked. The surface was strewn with abundant cohesive clots or aggregates of fine-grained regolith material ranging in diameter from 1 to 2 millimeters to a few centimeters. Many of the clots occupied small pits that probably were formed by the impact of the clots on the surface. The area is evidently a small patch or ray of secondary particles, but the probable source of the particles has not been determined. The precise spot from which the sample was taken apparently was not photographed after sample collection.

Samples 12043 and 12044. - Sample 12043 is a rock specimen collected on the south rim of the Surveyor Crater during the traverse between Halo Crater and the Surveyor III spacecraft. The rock appears to be resting mostly on the surface and has no clear-cut genetic relation to any of the surrounding surface features. Sample 12043 is the largest of three specimens collected at a spot where the astronauts observed a prominent double glass bead on the surface.

Sample 12044 is a soil sample that includes a double bead of glass. The glass has been identified in Hasselblad photographs AS12-48-7082 and AS12-48-7083 (fig. 6(c)) (taken by the LMP). The bead is 3 centimeters long and initially was included with the sample that was assigned the number 12044 after removal from sample bag 14-D in the LRL.

(c) Samples 12043 and 12044 before collection (AS12-48-7083).

Figure 6. - Continued.

Samples 12045, 12046, and 12047. - The sample locality for these three rock specimens was the northeast rim of Block Crater. The three samples probably are shown in Hasselblad photographs AS12-48-7148 to AS12-48-7150 (taken by the LMP) but have not been recognized so far. The locality is on the ejecta rim of a very fresh crater (Block Crater) that has been formed on the north wall of the Surveyor Crater and is characterized by abundant angular fragments. Most of the fragments probably
were derived from Block Crater, which was excavated, in turn, in the ejecta rim of the Surveyor Crater. Thus, these samples probably were derived ultimately from the Surveyor Crater and may have come from depths as great as several tens of meters at this locality on the Ocean of Storms.

Sample 12051. - Sample 12051 is one of the distinctive large fragments collected during the second EVA. The fragment is part of the blocky ejecta from a fresh 4 -meter-diameter crater on the south rim of the Surveyor Crater and is shown clearly in Hasselblad photographs AS12-49-7318 (fig. 6(d)) and AS12-49-7319 (taken by the LMP). The sample was picked up by hand by the CDR while the LMP steadied him with a strap from the tote bag. The site from which the sample was removed is shown in Hasselblad photograph AS12-49-7320. This specimen is characterized by a sheared surface on one side that was described by the astronauts. Part of both the sheared surface and the opposite convex surface of the specimen was buried in the regolith. The suggested selenographic orientation of sample 12051 is shown in figure 6(e).

(d) Sample 12051 before collection (AS12-49-7318).

Figure 6. - Continued.

(e) Suggested selenographic orientation of sample 12051.

Figure 6. - Continued.

The surface of sample 12051 exhibits three faces that have distinctly different shapes and weathering characteristics, indicating different exposure ages. Surface A (fig. 6(e)) is rounded and covered by many small glass-lined pits; surface B is apparently a fracture surface and displays only a few small pits; surface $C$ is flat and appears to be a freshly broken surface without pits. At the time of collection, the rock was standing on the small end approximately half embedded in the regolith.

Surface B on sample 12051 appears to be an older fracture face that probably resulted from another blow by impact at an earlier time. The minor pitting and weathering of surface B indicates postfracture exposure on the lunar surface before the event that formed surface $C$ and buried surface $B$.

The rounded heavily pitted appearance of surface A indicates a long period of exposure on the lunar surface for sample 12051. The two broken surfaces of different ages (surfaces B and C) attest to multiple bombardment and tumbling of the rock at or near the surface of the regolith.

The occurrence of this rock and other rounded and angular rocks in the rim of the rocky young crater indicates high probability that sample 12051 represents ejecta from the small crater - either from a fragmented impacting body or from displaced regolith or subregolith material at the impact site. In either case, the unpitted shear face probably resulted from the impact that formed the small crater. The angle of the specimen when found suggests that the rock fell into place together with enough surrounding fine material to hold it in position. Determining the exposure age of the portion of the flat side which was above the lunar surface might date the small crater.

Sample 12052. - Sample 12052, a large rock rounded on one side, was collected from the west rim of Head Crater and is shown clearly in Hasselblad photographs AS12-49-7217 and AS12-49-7218 (taken by the CDR) and AS12-48-7059 (taken by the LMP). The rock apparently was moved from the original site before the photographs were taken. Therefore, although the specimen can be oriented precisely with respect to the position in the photographs, the orientation shown in the photographs probably does not represent the orientation of the rock before it was disturbed. The lower angular part of the rock apparently was partially buried in the regolith, but the rock rested on the surface in the position shown in the photographs. A drag mark near the sample indicates the place from which the rock was removed. At least two pieces on one side of the specimen were broken off after the rock was photographed on the lunar surface and before it was photographed in the LRL. Sample 12052 is shown in figure 6(f) as it was photographed on the lunar surface and in figure 6(g) as it was photographed in the LRL with nearly identical orientation and shadow characteristics.

(f) Sample 12052 before collection (AS12-49-7218).

(g) Reconstructed selenographic orientation of sample 12052 (NASA-S-70-22673).

Figure 6. - Continued.

Sample 12053. - Sample 12053 is an angular fragment collected from the northwest rim of Bench Crater. The fragment appears to be part of a field of coarse fragments on the rim that probably were ejected from the crater. The specimen is identified readily in Hasselblad photographs AS12-49-7234 and AS12-49-7235 (taken by the CDR) and AS12-48-7063 (taken by the LMP). The rock was rotated out of the original position before the first photographs were taken; therefore, the original orientation is uncertain even though the site is well documented.

Sample 12054. - Sample 12054 is an unusual glass-coated rock collected a short distance south of the fresh 4-meter crater with which sample 12051 is associated. The astronauts believed that the rock may have been ejected from this small fresh blocky crater. The specimen is shown clearly in Hasselblad photographs AS12-49-7313 to AS12-49-7315 (fig. 6(h)) (taken by the LMP). In these photographs, the specimen can be seen to be resting on the surface. Three sides of the rock are coated with glass and two sides are free of glass. When photographed, the specimen was resting on one glass-free side; the other glass-free side was oriented toward the southeast. The field relations suggest that the rock was sprayed with glass in the position in which it was found on the surface and that the spray came from the west. Because the rock was found to exhibit shock damage in the LRL, an alternate possibility is that the glass was

(h) Sample 12054 before collection (AS12-49-7315).

Figure 6.- Continued.
sprayed onto the rock as it was ejected from an impact crater and, by coincidence, the rock landed on a side not coated with glass. The LRL reconstruction of the orientation and lighting as seen in the lunar-surface photograph of sample 12054 is shown in figure 6(i).

(i) Reconstructed selenographic orientation of sample 12054 (NASA-S-70-22696).

Figure 6. - Continued.

Sample 12055. - Sample 12055 is a tabular rock that is shown undisturbed before collection in Hasselblad photographs AS12-49-7197 (fig. 6(j)) and AS12-49-7198. The sample was moved slightly from the original position, as shown in photographs AS12-49-7199 and AS12-49-7200 (fig. 6(k)) (taken by the CDR) and AS12-48-7053 to AS12-48-7055 (taken by the LMP). After it was moved, the sample was described by the LMP as having a distinctly gray tone on the lower half (shown clearly in photograph AS12-48-7055). The color change apparently represented the line of burial; however, it is interesting to note in the undisturbed photograph (fig. 6(j)) that a fillet almost covers the northeast side of the rock to a point well above the reported line of color demarcation. This implies that the fillet may be relatively young in the exposure history of sample 12055 in the orientation in which it was collected, because no obvious color difference was related to the line of fillet burial.

(j) Sample 12055 (rock A) in undisturbed position before collection (letters A to E are for location reference in fig. 6(k)) (AS12-49-7197).

(k) Disturbed rock not sampled at site of sample 12055 (letters B to E are for location reference in fig. 6(j)) (AS12-49-7200).

Figure 6. - Concluded.

Sample 12056. - Sample 12056 is a tabular angular rock that has not been recognized in the surface photographs; however, the sampling locality has been tentatively placed near the Surveyor spacecraft. The rock is believed to be one of the four selected loose rock fragments described by the astronauts.

## Tote-Bag Samples

Sample 12062. - Sample 1.2062 is tentatively identified in Hasselblad photograph AS12-48-7139, which was taken near the Surveyor spacecraft. The rock is viewed from the southeast in the surface photographs, displaying the most rounded and densely pitted side of the rock. The rock appears to be about one-third buried, and a fillet is well developed on the east side.

Sample 12063. - Sample 12063 was the largest rock returned in the tote bag and, thus far, has not been recognized in any of the surface photographs.

Sample 12064. - Sample 12064 is a large rock that has a distinctively angular shape. This rock may be the one described by the astronauts as a square rock collected near the Surveyor spacecraft.

Sample 12065. - Sample 12065 has not been identified in the Hasselblad photographs but may be the "grapefruit" rock described by the CDR on the traverse between the ALSEP site and Head Crater early during the second EVA.

## SAMPLE INFORMATION

## Mineralogy/Petrology

Most of the large rock samples returned from the Apollo 12 mission are holocrystalline and have ranges of textures and mineralogical compositions that are characteristic of igneous origin. Two breccias also were returned. The crystalline rocks are similar to the Apollo 11 microgabbros and basaltic rocks in that they consist essentially of clinopyroxene, calcic plagioclase, olivine, and ilmenite. However, they contrast with the Apollo 11 suite in that they exhibit wide ranges in modal mineralogy, grain size, and texture.

Mineralogical composition. - The mineral species identified in the Apollo 12 samples are similar to those observed in the Apollo 11 materials. Glass, plagioclase, pyroxene, olivine, low cristobalite, ilmenite, sanidine, spinel, troilite, and iron ( Fe ) metal have been identified positively. Tridymite, metallic copper ( Cu ), and the Fe analog of pyroxmangite have been tentatively identified. X-ray data are presented in table VII.

Plagioclase is present in every rock sample and ranges from approximately 5 to 10 percent (sample 12075) to 70 percent (sample 12013). The estimates of composition were based on extinction-angle measurements and indices of refraction and range from $\mathrm{An}_{50}$ to $\mathrm{An}_{90}$, with the median value falling near $\mathrm{An}_{80^{\circ}}$. Although some plagioclase is
zoned, most is twinned. Lath-shaped crystals prevail, and pyroxene/plagioclase intergrowths are very common.

TABLE VI. - X-RAY DATA

${ }^{2}$ Numbers in parentheses indicate percent.
${ }^{b}$ Olivine sample.

Pyroxenes were identified by X-ray diffraction and by optical properties. Pigeonite and subcalcic augites are the most common, as determined optically. Refractive indices indicate that the ratio of Fe to Mg (magnesium) is about 0.5. Zoned pigeonite phenocrysts occur in porphyritic and coarse-grained rocks. Pigeonite occupies the core of some crystals, and subcalcic augite forms the rim. The subcalcic augite is a deeper brown than the pigeonite. The groundmass pyroxenes are fine grained, are darker than the phenocrysts, and are not zoned. Pyroxene/plagioclase
intergrowths are common and range in size from 1-centimeter-long crystals to aggregates in which the particles are only several microns across. Pyroxenes are the dominant minerals in all but three samples.

Olivine was identified by X--ray diffraction and by optical properties. The estimates of composition that were based on optics disagree with those that were based on X-ray data. The discrepancy was shown by spectrographic measurements to be caused by a fairly high calcium (Ca) content. The samples for which X-ray, optical, and spectrographic data are available indicate a composition of about $\mathrm{Ca} .05^{\mathrm{Mg}} .60^{\mathrm{Fe}} .35^{\circ}$. Oiivine commonly contains inclusions which are filled with devitrified glass or aggregates of plagioclase, pyroxene, and ilmenite. Some grains contain spherical-glass inclusions. Fayalite grains were tentatively identified by their optical properties. In contrast to the Apollo 11 rocks, olivine occurs in almost all of the Apollo 12 samples.

Low cristobalite occurs as interstitial aggregates and as euhedral to subhedral crystals.

Ilmenite was identified by XX-ray diffraction, by morphology, and by optical properties. The abundance ranges from less than 1 percent to 25 percent. In reflected light, some grains show intergrowths with an unidentified oxide phase.

The presence of spinel is suggested by the octahedral forms of opaque minerals of unknown composition that occur in olivine grains and in vugs. At least three other unidentified opaque phases also are present.

Troilite is a ubiquitous phase in all polished thin sections.
Metallic Fe occurs as interstitial blobs not commonly associated with troilite grains rather than as blobs in troilite as noted in the Apollo 11 rocks. It is more commonly associated with ilmenite than with any other phase.

Metallic Cu , tridymite, and the Fe analog of pyroxmangite were tentatively identified by optical methods.

Glass occurs as minute interstitial material in some crystalline rocks, as beads and groundmass in clastic rocks, and as a thin coating on several rocks.

Igneous rocks. - Approximately one-half of the igneous rocks have vesicles present, and all have vugs. The vesicles range in diameter from 0.1 to 40 millimeters and commonly are lined by tangentially or subparallel-oriented crystals of plagioclase, pyroxene, or olivine. The vugs contain euhedral crystals of pyroxene and olivine and less well-formed crystals of plagioclase, ilmenite, and spinel. The volume occupied by vugs and vesicles in any rock is generally less than that in the Apollo 11 rocks. The vugs are irregular and occur in the coarser rocks at the termination of the sheaflike aggregates of pyroxene and plagioclase. In one sample, pyroxene crystals appear in raised relief along a joint surface. Crystals in vugs and along joints are considerably coarser in grain size than the crystals in the groundmass minerals. Variations in cooling rates could be an explanation of the variety of grain sizes observed.

The grain size of the igneous rocks ranges from 0.05 to 35 millimeters. The textures show remarkable variations, many of which are common to volcanic and plutonic rocks on earth. Many of the rocks are equigranular gabbros, some are ophitic to subophitic diabases, and others are variolitic basalts. Feathering sheaves of pyroxene/plagioclase intergrowths are found in the groundmass of porphyritic rocks containing phenocrysts of pigeonite. The olivine crystals in more rocks are equant euhedral grains that are somewhat coarser than the groundmass.

The mineralogical composition of the igneous rocks reflects the high FeO content. The lower $\mathrm{TiO}_{2}$ contents (compared to the Apollo 11 rocks) are reflected in the smaller amounts of ilmenite. The textural and mineralogical variations can be explained readily by fractional crystallization and mineral accumulation during the cooling of basaltic magmas.

The modal mineralogy shows a wide variation (fig. 7), especially when contrasted with the Apollo 11 modes. The modes range from peridotites (sample 12075: 50 percent pyroxene, 40 percent olivine, and 10 percent plagioclase), olivine gabbros

Figure 7. - Apollo 11 and 12 lunar-sample modal analyses.
(sample 12036: 25 percent pyroxene, 40 percent olivine, and 25 percent plagioclase), and gabbros (sample 12052: 40 percent pyroxene, 30 percent plagioclase, 15 percent olivine, and 15 percent opaque minerals) to troctolites (sample 12035: 15 percent pyroxene, 40 percent olivine, and 45 percent plagioclase) to picritic basalts (sample 12045).

Sample 12013, which consists largely of plagioclase and sanidine, appears to be a late-stage differentiate on the basis of the modal mineralogy and trace-element content.

Some rocks show evidence of planar features (such as fractures and lines of vugs) but the rocks are generally without marked foliation or lineation. All of the rocks are fresh and show no evidence of the hydration or oxidation reactions common during latestage terrestrial magmatic processes.

Breccias. - One rock is a fragmental breccia that is similar to the Apollo 11 breccias (ref. 1). Two breccia chips also were collected. The dominant constituents of the breccias appear to be pyroxene and plagioclase with accessory olivine and glass. Lithic fragments also are present. The average mineralogical composition appears to be less olivine-rich than the majority of rock types collected. The fragmental breccia appears to have a foliation in which both lithic and mineral fragments are subparallel. The lithic fragments are as large as 20 by 10 millimeters and are both igneous and fragmental rocks, indicating several periods of fragmentation and consolidation.

Fines. - The Apollo 12 lunar fines contrast with the Apollo 11 fines in that they consist of different proportions of phases and, consequently, are lighter in color. The major constituents (in decreasing order of abundance) are pyroxene, plagioclase, glass, and olivine. The minor constituents, which total only a few percent, are ilmenite, tridymite, cristobalite, nickel ( Ni ) Fe , and several unidentified phases. The Fe analog of pyroxmangite was tentatively identified.

Glass totals roughly 20 percent of the Apollo 12 fines and includes spheroidal and dumbbell-shaped objects and angular fragments. The color of the glass ranges from colorless through pale yellow brown and brown to dark brown; the index of refraction generally ranges from 1.55 to 1.75 . Bubbles and solid inclusions are common in the colored glasses. In contrast to the Apollo 11 fines, feldspar glass, dark to nearly opaque spheroidal glass, and dark scoriaceous glass fragments are relatively rare.

The pyroxenes, mostly pale yellow to tan and brown, range widely in composition and include augite, subcalcic augite, and pigeonite. They constitute about 40 percent of the fines. The range of the indices of refraction is somewhat greater than that of the pyroxenes of the Apollo 11 fines. Plagioclase has indices of refraction mostly in the bytownite/anorthite range. A small amount of more sodic plagioclase also is present. The olivine totals approximately 5 to 10 percent and is more abundant than in the Apollo 11 fines. The few carefully measured grains fell in the compositional range $\mathrm{Fo}_{60-70^{\circ}}$ Many lithic fragments are present. Low tridymite is in the form of anhedral grains, and the low cristobalite occurs as microgranular aggregates.

There are two fines samples of notably different character: (1) the light-colored layers in the double core tube and (2) sample 12033, a documented fines sample
collected from a trench dug near the northwest rim of Head Crater. The color of both samples is light gray. Sample 12033 consists of clear, angular grains of feldspar with some olivine and pyroxene and abundant basaltic glass. The coarser 1 -millimeterdiameter glass fragments are pumiceous, exhibiting well-developed flow structure and stretched vesicles, and the finer fragments are angular and somewhat vesicular. The finer shards also show a flow structure consisting of oriented microlites. Sample 12033 is tentatively considered a crystal-vitric ash.

A significant feature of the fines is the presence of numerous very well-rounded grains that have minutely chipped surfaces and that resemble grains in terrestrial detrital sands. Many of the grains are slightly elongate oblate bodies with a beanlike shape and occur in size to well below 0.1 millimeter. Presumably the result of mechanical abrasion, the grains are chiefly glass; however, some are composed of pyroxene, plagioclase, or intergrowths of these minerals.

Rock-surface features. - Most of the larger Apollo 12 crystalline rocks are similar to the Apollo 11 rocks in that they are rounded on one surface and have glass-lined pits. Angular fractured surfaces occur on some of the rocks.

Small pits (similar to those described in ref. 1) occur on the rock surfaces; the density ranges from 1 to $30 \mathrm{pits} / \mathrm{cm}^{2}$. The angular bottom surfaces have few or no pits. The pits that are visible under a binocular microscope range from 0.1 to 10 millimeters in diameter and the depth-to-width ratios are approximately 1: 5. Most of the pits are circular; exceptions are the oval-shaped pits in the coarse crystalline rocks that have the long axis parallel to elongated feldspar or pyroxene crystals. The glass linings of the pits vary greatly in thickness and vesicularity. Pulverized minerals form 0.5 - to 1.0 -crater-width white halos around the pits on the crystalline rock surfaces. Where pit density is high, a 1 - to 2 -millimeter-thick crust of pulverized minerals is formed on the rock surface. Impact pits in glass coatings are surrounded by radiating fractures. On many of the medium- to coarse-grained crystalline rocks, the glass linings of the pits are raised slightly above the rock surface. These glass-topped pedestals appear to be more resistant to erosion than the rock.

Irregular patches of glass are spattered on the rock surfaces. Two types (which grade into one another) can be distinguished: thin films and thick, highly vesicular coatings. The thin (less than 0.1 millimeter thick) films are brownish black in reflected light and brown in transmitted light, cover a 1 - to 16 -square-centimeter area, are usually slightly vesicular, and adhere tightly to the rock surface. The thick ( 0.1 to 1 centimeter) coatings, which were found on samples from the bottom of a 1-meter crater, are light to dark brown, have vesicle sizes increasing from 0.1 to several millimeters from the base to the outer surface, and have smooth botryoidal surfaces. Several highly fractured breccias and fine-grained crystalline rocks are covered with the thick coating. The fractures in these rocks are filled to a depth of several centimeters. The contacts between the glass and the rock are sharp. The glass coatings locally contain a large number of angular, highly shocked rock chips. Some of the vesicular glass has been partly devitrified. A light-gray glass fragment of uncertain origin with pronounced flow structure also was collected.

Impact metamorphism. - Irnpact metamorphism in the Apollo 12 samples is similar to and as common as in the A.pollo 11 samples. Impact-fused glass spherules and beads and shock-vitrified mineral fragments are present both in the fines and in the microbreccias.

Most of the large crystalline rocks apparently are unshocked or only weakly shocked; several of the smaller crystalline rocks show evidence of moderate to strong shock. A thin section of one of the smaller rocks shows extensive fracturing of the plagioclase and partial vitrification and development of lamellar microstructures. The coexisting clinopyroxenes have one or two sets of closely spaced lamellar twinning that are absent in the clinopyroxene of similar unshocked crystalline rocks. Another rock shows extensive shock vitrification.

Shocked microbreccia also is present in the Apollo 12 samples. Many small fractured microbreccia fragments are held together by glass spatters. Breccia within breccia, indicating a multiple-shock history, also was found.

Small pebbles were collected that are either glassy or aphanitic. The pebbles are highly vesicular and some are vuggy. The pebbles are presumably the result of melting and fragmentation caused by impact metamorphism. Some of the vesicles are as large as 10 millimeters in diameter and occupy up to 50 percent of the preserved fragment.

## Chemical Analyses

Chemical analyses of the samples were conducted inside the biological barrier of the LRL, mainly by optical spectrographic techniques, using an instrument with a dispersion of $5.2 \AA / \mathrm{mm}$. Three separate techniques were conducted as follows.

1. Determination of silicon ( Si ), titanium ( Ti ), aluminum ( Al ), $\mathrm{Fe}, \mathrm{Mg}$, cobalt (Co), manganese (Mn), chromium (Cr), sodium ( Na ), and potassium ( K ) with Sr used as the internal standard
2. Determination of $\mathrm{Mn}, \mathrm{Cr}$, zirconium (Zr), Ni, Co, scandium ( Sc ), vanadium $(\mathrm{V})$, barium ( Ba ), Sr, yttrium (Y), and ytterbium (Yb) and other involatile elements, using palladium (Pd) as the internal standard
3. Determination of lithium ( Li ), rubidium ( Rb ), Pb , boron (B), and other volatile elements, using Na as the internal standard

The procedures were generally similar to those used to analyze the Apollo 11 samples; however, as a result of the experience with the Apollo 11 material, modifications were made to cope more effectively with the high concentration of the refractory elements. For example, the ratio of admixed carbon (C) to the sample was increased from 1:1 to 4: 1 for the method using Pd as the internal standard, and the range of possible intensity measurements was increased by a factor of 3 , enabling a wider range of concentrations to be covered effectively (for example, Ba and Zr ). The reduction of a sample to a powder was done in Spex agate vials in a mixer mill, in contrast to handgrinding in agate mortars for the Apollo 11 samples.

Computer programs were used to provide intensity data from the photoplate densitometer data, in contrast to the hand processing of the Apollo 11 data. The overall precision of the determinations is $\pm 5$ to 10 percent of the amount present. Accuracy of the results was controlled by use of the international rock standard samples (G-1, W-1, SY-1, BCR-1, AGV-1, GSP-1, G-2, PCC-1, and DTS-1) for calibration. In addition, the results were compared with the analyses of the Apollo 11 samples.

The spectrographic plates were examined to establish the presence or absence of all elements that have spectral lines in the wavelength regions covered ( 2450 to $4950 \AA$ and 6100 to $8600 \AA$ ). Line interferences were checked for all lines (in particular by elements such as $\mathrm{Ti}, \mathrm{Cr}, \mathrm{Y}$, and Zr ) present in high concentrations compared to most terrestrial rocks. Wavelengths of the several principal lines were checked for those elements that were not detected because line interferences caused by common elements were occasionally visible. Several samples were brought from behind the biological barrier and analyzed by atomic absorption procedures for $\mathrm{Al}, \mathrm{Ca}, \mathrm{Mg}, \mathrm{Fe}, \mathrm{Ti}, \mathrm{Na}$, and K , and by a chemical colorimetric procedure for Si . The data reported for these elements in sample 12013 were obtained by these methods. The spectrographic data are presented in tables VIII to XI and the atomic absorption data in table XII. The sample weights provided for analysis were larger than for the Apollo 11 suites and were typically 100 to 150 milligrams.

The samples appear to be free from inorganic contamination, either from the rock box or from the LM. Niobium (Nb), which constitutes 88 percent of the LM descent-engine skirt, was detected in only two samples, sample 12013 with 170 ppm and sample 12033 with 44 ppm . This amount is almost certainly indigenous to the rocks and is geochemically consistent with the high abundance of the geochemically associated elements Zr and Y . Indium, present in the seal of the rock boxes, was not detected (the detection limit was 1 ppm ). Values for Cu are not reported for the Apollo 12 rocks. Sporadic contamination of the samples (up to several hundred ppm) was found because of abrasion of the copper parts of the door mechanisms in the class III biological cabinets where the sample preparation work was done.

${ }^{\mathrm{a}}$ The data for $\mathrm{SiO}_{2}$ were obtained by spectrophotometric analysis.

The major constituents of the samples are (in order of decreasing abundance) Si , $\mathrm{Fe}, \mathrm{Mg}, \mathrm{Ca}, \mathrm{Al}$, and Ti . The major silicate and oxide mineral phases present in the samples indicate that O comprises the major anion. The elements $\mathrm{Cr}, \mathrm{Na}, \mathrm{Mn}$, and K are the minor constituents and have concentrations ranging from 0.05 to 0.6 percent; occasionally, Ba and Zr reach these concentration levels. The other constituents are present mostly at less than 200 ppm ( 0.02 percent). The volatile elements ( $\mathrm{Pb}, \mathrm{B}$, bismuth ( Bi ), thallium ( Tl ), and so forth) are generally below the limits of detection of the spectrographic methods used, although Pb (approximately 30 ppm ) and B (approximately 20 ppm ) were detected in sample 12013. Gold, silver, and the platinum-group elements were not detected in any samples.

The chemistry of the crystalline rocks is distinct from that of the fines material and the breccias. The rocks are lower in $\mathrm{Rb}, \mathrm{K}, \mathrm{Ba}, \mathrm{Y}, \mathrm{Zr}, \mathrm{Ni}$, and Li and higher in Fe and Cr. Several critical element ratios are also distinct. The K/Rb ratio averages 850 in the rocks compared to 450 in the fines. The average $\mathrm{Fe} / \mathrm{Ni}$ ratio of 3000 in the rocks (range from 2000 to 11000 ) is much higher than the fines material ratio of approximately 600 . The $\mathrm{Rb} / \mathrm{Sr}$ ratio is very low in the rocks $(0.005)$ but is higher in the fines (0.02).

The fines material and the breccias are generally very similar in composition and could not have been formed directly from the large crystalline-rock samples. The Ni content of the breccias and fines material places an upper limit on the amount of meteoritic material contributed to the lunar-surface regolith. Using an average meteoritic Ni content of 1.5 percent, the Ni content of the fines material represents a meteoritic contribution of the order of 1 percent if all the Ni were extralunar.

The crystalline rocks show minor but significant internal variations in chemistry. Nickel shows a striking decrease in concentration, by an order of magnitude. Chromium displays a smaller relative decrease in the same direction, and Co shows a slight decrease. Silicon increases as Mg decreases. Similar trends are shown by V, Sc, Zr, $\mathrm{Y}, \mathrm{K}, \mathrm{Ba}$, and Ca , although the variations are small. Critical element ratios ( $\mathrm{Fe} / \mathrm{Ni}$, $\mathrm{Ni} / \mathrm{Co}$, and $\mathrm{Cr} / \mathrm{V}$ ) decrease, and the $\mathrm{V} / \mathrm{Ni}$ ratio increases with a decrease in Mg. No significant trends are shown by $\mathrm{K} / \mathrm{Rb}, \mathrm{Rb} / \mathrm{Sr}$, or $\mathrm{K} / \mathrm{Ba}$ ratios.

Sample 12013 is chemically unique. It is not analogous chemically to a terrestrial anorthosite. The sample contains the highest concentration of silicon oxide ( $\mathrm{SiO}_{2}$ ) ( 61 percent) yet observed in a lunar rock. The amounts of $\mathrm{K}, \mathrm{Rb}, \mathrm{Ba}, \mathrm{Zr}, \mathrm{Y}, \mathrm{Yb}$, and Li are enriched by 10 to 50 times compared to the other rocks. These high concentrations are suggestive of the terrestrial enrichment of elements in residual melts during the operation of fractional-crystallization processes, and the sample may have crystallized from a small volume of residual melt late in the cooling of a pool of silicate melt. The ferromagnesian elements ( $\mathrm{Mg}, \mathrm{Fe}, \mathrm{Cr}, \mathrm{Mn}, \mathrm{Ti}, \mathrm{Sc}$, and Co ), although low in sample 12013 in comparison with the other rocks, are not strikingly depleted. Nickel, in particular, is not depleted as it would be in terrestrial analogs. Sample 12033 from the light-gray fines material shows some analogs in composition that contain high concentrations of $\mathrm{Yb}, \mathrm{Nb}$, and Rb .

A comparison of the Apollo 12 samples from the Ocean of Storms with the Apollo 11 samples from the Sea of Tranquility shows that the chemical characteristics of the samples at the two maria sites are clearly related. Both suites show the distinctive features that most clearly distinguish lunar from other material - high concentrations of 'refractory' elements and low concentrations of volatile elements. In
detail, numerous and interesting chemical differences exist between the Apollo 12 and the Apollo 11 rocks. The main differences are as follows.

1. The Apollo 12 rocks and fines material have a lower concentration of Ti . The range is 0.72 to 3.4 percent Ti ( 1.2 to 5.1 percent $\mathrm{TiO}_{2}$ ) compared with the range in the Apollo 11 rocks of 4.7 to 7.5 percent Ti ( 7 to 12 percent $\mathrm{TiO}_{2}$ ).
2. The Apollo 12 samples have lower concentrations of $\mathrm{K}, \mathrm{Rb}, \mathrm{Zr}, \mathrm{Y}, \mathrm{Li}$, and Ba.
3. The Apollo 12 crystalline rocks have higher concentrations of $\mathrm{Fe}, \mathrm{Mg}, \mathrm{Ni}$, Co, V, and Sc. These concentrations are consistent with the more mafic character of the Apollo 12 rocks.
4. The significant variation in the Apollo 12 rocks is among the ferromagnesian elements, entering the principal mineral phases. In the Apollo 11 suite, a much wider variation existed in the concentration of elements such as K and Rb , indicating a wider range of crystallization. However, sample 12013 represents a much more extreme composition (and probable later crystal fraction) than that of any of the Apollo 11 rocks.
5. The fines material collected at the Apollo 12 site differs from that collected at the Apollo 11 site in that it contains approximately half the Ti content; more Mg ; and possibly higher amounts of $\mathrm{Ba}, \mathrm{K}, \mathrm{Rb}, \mathrm{Zr}$, and Li . The light-gray fines material of sample 12033 is strongly enriched in $\mathrm{Rb}, \mathrm{Zr}, \mathrm{Yb}$, and Nb relative to the other fines material.

The chemistry of the Apollo 12 samples does not resemble that of chondrites. Nickel, in particular, is strikingly depleted. The samples are closest in composition to the eucrite class of the basaltic achondrites; sample 12038 shows some similarities to this class (table X). The possible 'lunar acid" rock (sample 12013) does not resemble terrestrial granites or rhyolites or even tektites in the abundances of most elements. The Apollo 12 material is enriched in many elements by one to two orders of magnitude in comparison with estimates of cosmic abundances.

## Gamma-Ray Spectrometry Analyses

Operation of the radiation-counting laboratory (RCL) followed the general procedures developed for the Apollo 11 studies (ref. 1). The first RCL sample was received for measurement on November 30, 1969, and probably would have been received approximately 1 day earlier if a glove failure had not delayed operations in the vacuum laboratory. Because of the experience gained during the Apollo 11 analyses, the preparation of samples for the RCL generally was completed more rapidly and at more regular intervals.

For the RCL analyses, 11 samples were chosen from the contingency sample, the selected samples, the documented sample box, the documented sample bags, and the tote-bag samples. Analysis was performed by use of the NaI(Tl) low-background spectrometer and the on-line computer data-acquisition system described in reference 1. The samples were mounted in stainless steel cans that had 16.2-centimeter diameters,
0.8 -millimeter wall thicknesses, and bolt-type indium seals. Standard containers with overall heights of 5.6 or 7.6 centimeters were used for all rock samples. The fines were packaged in a cylindrical container, which was used in searches for magnetic monopoles.

For this preliminary study, calibrations were obtained with a series of radioactive standards prepared by dispersing known amounts of radioactive material in quantities of Fe powder. Time did not permit recording a library of standard spectra with the standard sources placed inside the actual steel containers. Therefore, empirical corrections for the effects of the containers were made; these corrections were least important for the ${ }^{40} \mathrm{~K}$ data and most serious for the ${ }^{26} \mathrm{Al}$ and ${ }^{22} \mathrm{Na}$ data.

The results of the analyses are summarized in table XIII. Because of the preliminary nature of the investigation, rather large errors were assigned. In addition to the statistical errors of counting, these errors include estimates of possible systematic errors caused by uncertainties in the detector-efficiency calibration.

Although many qualitative similarities exist between the RCL data on the Apollo 11 and the Apollo 12 samples, some notable differences also exist. The $K$ concentration of the Apollo 12 crystalline rocks is remarkably constant at about 0.05 percent, and the ratio of $K$ to uranium ( $U$ ) is about 2200. These properties appear to be significantly lower than for the typical crystalline rocks from Apollo 11; however, the composition

[^0]of one of the coarsely crystalline Apollo 11 rocks (sample 10003) very closely resembled the chemical composition of the crystalline rocks shown in table XIII. The ratio of thorium (Th) to $U$ is approximately 4 for all typical materials in table XIII, the same as for the materials from the Sea of Tranquility. The concentrations of the radioactive elements $\mathrm{K}, \mathrm{Th}$, and U in the crystalline rocks of table XIII are all remarkably constant and, on the average, much lower than for the comparable Apollo 11 rocks. Because so few samples from the two sites can be compared, the factor of biased sampling of the lunar-surface material cannot be discounted.

The breccias and fines are very different from the crystalline rocks in several respects. The $\mathrm{K} / \mathrm{U}$ ratio for the breccias and fines is only 1400 to 1500 , compared with an average of approximately 2800 for the Apollo 11 materials. Thus, the Apollo 12 samples show even greater differences from terrestrial rocks and meteorites than did the surface material from the Sea of Tranquility. Although the Th/U ratio remains at approximately 4, the concentrations of all radioactive elements are much higher in the breccias than in the crystalline rocks.

In general, the amount of cosmogenic ${ }^{26} \mathrm{Al}$ and ${ }^{22} \mathrm{Na}$ appears to be saturated but shows variations that may be related to chemical composition or to cosmic-ray exposure. For example, sample 12034 was collected from a trench dug during the second EVA and was buried approximately 10 to 20 centimeters. The saturation activities of ${ }^{26} \mathrm{Al}$ and ${ }^{22} \mathrm{Na}$ are reduced by the amount expected because of attenuation of the irradiation flux in the lunar soil.

## Noble Gas Results

Several samples each of the fines material, breccias, and crystalline rocks returned by the Apollo 12 astronauts have been analyzed for noble gas isotopes. The analyses were performed by mass spectrometry, and the general procedures were the same as for the preliminary examination of the Apollo 11 samples (ref. 1). Similar to the Apollo 11 materials, the Apollo 12 fines and breccias are characterized by large abundances of noble gases of solar-wind origin, as exemplified by the large relative abundances of He and by the characteristic ${ }^{4} \mathrm{He} /{ }^{3} \mathrm{He}$ and ${ }^{20} \mathrm{He} /{ }^{22} \mathrm{He}$ ratios. Conversely, the crystalline rocks contain much smaller amounts of the noble gases that arise mainly from spallation reactions within the samples or from radiogenic decay. The noble-gas isotopic contents for typical samples of all three types of the Apollo 12 lunar material are listed in table XIV. The ratios are believed to be accurate to within $\pm 2$ percent (except ${ }^{4} \mathrm{He} /{ }^{3} \mathrm{He}$, which has a larger uncertainty) and the abundances to within $\pm 20$ percent (except ${ }^{84} \mathrm{Kr}$ (krypton), which is considerably greater).

Despite the general similarity in the noble gas content of the Apollo 12 and Apollo 11 material, several real and significant differences exist. The noble gas contents (in cc/g at STP) of the Apollo 12 fines and breccias are lower; the fines by a factor of 2 to 5 and the breccias by an order of magnitude. Using a model of formation of the fines material by (1) degradation of surface rock, (2) surface irradiation by constant solar wind, and (3) subsequent burial by additional fines material, the lower gas content of the fines implies a higher accumulation rate of material. The gas content of the

Apollo 12 breccias is lower than that of the Apollo 12 fines by approximately a factor of 2, which constitutes a reversal of the trend observed with the Apollo 11 material and implies that the Apollo 12 breccias were formed from fines material of lower solarwind gas content. The breccias apparently were formed at some distance or depth from the location at which they were collected.

For sample 12034 (a breccia), the total noble gas content is low enough for a spallation component to be quite evident. Sample 12010 is an unusual breccialike rock that was identified on the basis of the noble gas content. The rock is characterized by a large relative abundance of the lithic phase, with the darker fine-grained material occurring as veins. The dark phase of sample 12010 contains approximately 70 percent of this fine-grained material, while the light phase is essentially pure lithic material. The typical breccialike nature of sample 12010, in terms of the noble gas content, is obvious.

The ${ }^{40} \mathrm{Ar} /{ }^{36} \mathrm{Ar}$ ratio in the Apollo 12 fines and breccias (with the exception of sample 12010) is lower than that for Apollo 11, although the ratio still shows larger values for breccias than for fines. Theoretical considerations prohibit ${ }^{40} \mathrm{Ar} /{ }^{36} \mathrm{Ar}$ ratios
even as large as 0.6 for the sun, making a solar-wind origin of the ${ }^{40} \mathrm{Ar}$ unlikely. The amount of ${ }^{40} \mathrm{Ar}$ in the fines is too large to be generated by in situ decay of K ; however, for the breccias, this mode of origin may be possible. The fines material thus appears to have acquired excess ${ }^{40} \mathrm{Ar}$ of lunar origin. The amount of ${ }^{40} \mathrm{Ar}$ and the ${ }^{40} \mathrm{Ar} /{ }^{36} \mathrm{Ar}$ ratio in sample 12010 demonstrate this phenomenon well. Although the lithic phase resembles the other crystalline rocks in Ar content, the fine-grained material shows not only large amounts of solar-wind Ar but also large excesses of ${ }^{40} \mathrm{Ar}$.

The crystalline-rock samples discussed in this section are completely interior chips and contain noble gas several orders of magnitude less than the fines material. The exceptions are ${ }^{3} \mathrm{He},{ }^{21} \mathrm{Ne}$ (neon), ${ }^{40} \mathrm{Ar}$, and some of the lighter isotopes of Kr and xenon (Xe), isotopes the abundances of which have been greatly increased by spallation reactions and radioactive decay. By use of the K concentrations obtained for the rocks by the chemical analysis group of the PET, the K-Ar ages were calculated. Several crystalline rocks show ages between 1.7 and 2.7 billion years, with an average age of 2.3 billion years. Sample 12013 has a unique chemical composition, characterized in part by much higher abundances of $K$ and $U$ and, consequently, of radiogenic ${ }^{4} \mathrm{He}$ and ${ }^{40} \mathrm{Ar}$. The sample also contained excess radiogenic ${ }^{40} \mathrm{Ar}$, rendering the $\mathrm{K}-\mathrm{Ar}$ age meaningless. However, the $\mathrm{U}-{ }^{4} \mathrm{He}$ and $\mathrm{Th}-{ }^{4} \mathrm{He}$ ages are consistent with a value of approximately 2.3 billion years, as is the case for many of these crystalline rocks. This age is considerably less than that found for the Apollo 11 crystalline rocks, although the range of ages for the two sites overlaps. At least this portion of the Ocean of Storms apparently has a more recent crystallization age than the rocks from the Sea of Tranquility, which implies that lunar maria have a formation history of at least 1 billion years.

Cosmic-ray exposure ages (that is, integrated exposure time at the lunar surface) were calculated for several rocks on the basis of $2 \pi$ geometry and of a ${ }^{3}$ He production rate of $1 \times 10^{-8} \mathrm{ccSTP} / \mathrm{g} / 10^{6}$ years. These ages show the much wider range of 1 to 200 million years, with some apparent grouping of ages, and resemble the ages found for the Apollo 11 rocks. The breccias also show radiation ages in this range. Spallation-produced isotopes other than ${ }^{3} \mathrm{He}$ are consistent with the ${ }^{3} \mathrm{He}$ ages and with the special chemistry of the lunar material. Because of the abundances of high-alkaline earth, Y , and Zr , spallation-produced Kr and Xe are very obvious in the rocks. The amounts of these gases are also roughly consistent with the chemical composition.

## Total Carbon Analyses

The total C content of the lunar samples was determined using $O$ combustion followed by gas-chromatographic detection of the $\mathrm{CO}_{2}$ produced. Samples weighing from 50 to 600 milligrams were placed with Fe chips and a copper-tin accelerator in a preburned refractory crucible. The crucible was then heated to more than $1600^{\circ} \mathrm{C}$ in an $O$ atmosphere with an induction heater. The combustion products were carried by the O through a dust filter to remove metal oxides and through a manganese oxide trap to
remove sulfur (S) gases. Any carbon monoxide (CO) that was formed was converted to $\mathrm{CO}_{2}$ in a heated catalyst tube. Moisture was removed by an anhydrone trap before the $\mathrm{CO}_{2}$ was passed into a LECO No. 589-600 Analyser. The $\mathrm{CO}_{2}$ was carried by the O stream into a collection trap. After a fixed collection time, the trap was heated and the released $\mathrm{CO}_{2}$ was carried by He through a silica-gel column into a thermal-conductivity measuring cell. The detection method used the difference in thermal conductivity between He and $\mathrm{CO}_{2}$. The imbalance in the bridge circuit containing the thermalconductivity cell was integrated and read directly on a digital voltmeter.

The system was calibrated using the National Bureau of Standards Steel Standard 101 e . Samples of this standard containing 5 to 50 micrograms of $C$ were run under the same conditions as the lunar samples. To reduce the background, the crucible was burned in air at $1000^{\circ} \mathrm{C}$ for at least 1 hour. Only crucibles from a single burn batch were used in a sequence of standards and samples. The precision of the method was evaluated by making replicate runs on sample blanks. A typical standard deviation on a series of 10 runs was 2 micrograms of total C. At all times, the samples were handled as little as possible to reduce laboratory contamination. The results for the standard samples were plotted on linear graph paper, and the C content in the lunar samples was read directly from the standard linear curve.

The results of the total $C$ analyses are given in table XV. The highest $C$ abundances, as for the Apollo 11 samples, usually are found in the fines. The exceptions to this generalization are samples 12032 and 12033, which are fines from the bottoms of trenches. The breccias have more $C$ than the igneous rocks, which (including the heavily shocked sample 12052) are consistently low in C. A total C abundance of approximately 40 ppm appears to be indigenous to lunar rocks. Additional C apparently was added to the fines and subsequent breccias by meteoritic impact, the solar wind, and possible contamination. The low abundances even in the fines material indicate that C has not accumulated to any great degree. The total C results alone give no indication of the specific chemical species present.

## Organic Mass-Spectrometry Analyses

A complete description of the system used for acquiring and presenting the mass spectral data from the organic analyses of the Apollo 11 samples is given in reference 1. The same procedures were used for the Apollo 12 mission with the following modifications.

1. Because of the problems encountered in the Apollo 11 analyses with the sterilization procedures necessary for sample transfer from the various sample-handling facilities to the mass spectrometer, a different approach was used. All samples were placed in previously cleaned stainless steel containers that were sealed (gastight) with aluminum caps. The containers were dry-heat sterilized at $130^{\circ} \mathrm{C}$ for 30 hours and
then transferred to the gas-analysis laboratory (GAL). This method eliminated the previous problems with the peracetic acid and ethylene oxide sterilization agents. The sample-transfer containers were opened and samples were handled in a clean nitrogen glove box in the GAL. All samples were put into a single Ni capsule. The same capsule was used for all the analyses, thus eliminating the contamination caused by improperly cleaned Ni capsules. To shorten the sample run time, the Ni capsule was cooled in Freon between runs; this procedure introduced the very slight amount of $\mathrm{m} / \mathrm{e} 84$ and 86 that is apparent in the mass spectra of some samples.
2. New programs were added to the system to allow plotting of a specific mass intensity as a function of the scan number. Some of these plots are included in appendix $B$ in the data associated with each sample and are labeled with the particular mass chosen (for example, m/e 44).
3. The summarization plots presented in appendix B give the ion current as a function of the scan number. The following masses have been deleted from the Apollo 12 summary: m/e 14, 16 to $20,23,26$ to $28,32,35$ to 37,40 , and 44 .

Both shallow and deep core-tube samples, coarse- and fine-grained rocks, a breccia, and other fines material and random chips have been analyzed. The following statements can be made with respect to all analyses. In general, the samples are very clean (much cleaner than the Apollo 11 samples), with only one sample (sample 12059-1) contaminated severely. The most striking feature of all of the organic analyses is the liberation of relatively large amounts of CO and $\mathrm{CO}_{2}$ during the sample runs. The characteristics of the evolution of these gases indicate that they are the result of a pyrolysis process. This feature may have been true of the Apollo 11 samples also; however, no effort was made to monitor CO and $\mathrm{CO}_{2}$ during the Apollo 11 analyses.

## Organic-Monitor Analyses

The analytical results of the various Apollo 12 organic monitors (OM), both from the ALSRC and from the Ottawa sand used to monitor the LRL processing, are presented in appendix $C$. The data in appendix $C$ comprise the most significant information available on the Apollo 12 contamination history. All tools used for the Apollo 12 sample processing were cleaned at the NASA White Sands Testing Facility and are assumed to have the same amount and type of contaminants as the Apollo 11 tools.

The principal organic monitors used for the S-ALSRC and the D-ALSRC were the York-mesh samples. The results given in appendix $C$ include only the data for the coupons removed during the outbound processing. The coupon that remained in each ALSRC for the entire flight will be analyzed. The organic-contamination potential was reduced notably during the Apollo 12 lunar-sample processing, as evidenced by the use of the processing cabinets and by the very low levels (less than 1 ppm ) of organic material added to the monitors by exposure to the processing cabinets.

## CONCLUSIONS

The major findings of the preliminary examination of the Apollo 12 lunar samples are the same as the conclusions reached from the examination of the Apollo 11 samples. The major findings are as follows.

1. The fabric and mineralogy of the rocks divide them into two genetic groups: fine- and medium-grained crystalline rocks of igneous origin (probably originally deposited as lava flows, then dismembered and redeposited as impact debris) and breccias of complex history.
2. The modal mineralogy and bulk chemistry of the crystalline rocks show that they are different from any terrestrial rock and from meteorites.
3. Erosion has occurred on the lunar surface because most rocks are rounded. Some rocks have been exposed to a process that gives them a surface appearance similar to that of sandblasted rocks. There is no evidence of erosion by surface water.
4. The probable presence of the iron-troilite-ilmenite assemblage and the absence of any hydrated phase suggest that the crystalline rocks were formed under extremely low partial pressures of oxygen, water, and sulfur (in the range of those in equilibrium with most meteorites).
5. The absence of secondary hydrated minerals suggests that there has been no surface water at the Sea of Tranquility or the Ocean of Storms at any time since the rocks were exposed.
6. Evidence of shock or impact metamorphism is common in the rocks and fines.
7. All the rocks display glass-lined surface pits that may have been caused by the impact of small particles.
8. The level of indigenous organic material capable of volatilization or pyrolysis (or both) appears to be extremely low (that is, no more than 10 to 200 ppb ).
9. Elements that are enriched in iron meteorites (that is, nickel, cobalt, and the platinum group) either were not observed or were very low in abundance.
10. Of the 12 radioactive species identified, two were cosmogenic radionuclides of short half-life; namely, ${ }^{52} \mathrm{Mn}$ ( 5.7 days) and ${ }^{48} \mathrm{~V}$ ( 16.1 days).
11. The uranium and thorium concentrations are near the typical values for terrestrial basalts; however, the ratio of potassium to uranium determined for lunarsurface material is much lower than those ratios determined for either terrestrial rocks or meteorites.
12. The fines material and breccias contain large amounts of all the noble gases that have elemental and isotopic abundances that are almost certainly indicative of
solar-wind origin. The fact that interior samples of the breccias contain these gases implies that the samples were formed at the lunar surface from material previously exposed to the solar wind.
13. The high ${ }^{26} \mathrm{Al}$ concentration observed is consistent with the long exposure age to cosmic rays inferred from the rare-gas analyses.
14. No evidence of biological material has been found in the samples to date.
15. The lunar soil at the landing site is predominantly fine-grained, granular, slightly cohesive, and incompressible. The soil is similar in appearance and behavior to the soil at the Surveyor landing sites.

The following differences were observed in the examinations of the Apollo 12 and Apollo 11 lunar samples.

1. The Apollo 12 crystalline rocks show a wide range in both texture and mode, whereas the Apollo 11 crystalline rocks had essentially one texture (lath-shaped ilmenite and plagioclase with interstitial pyroxene) and similar modes ( 50 percent pyroxene, 30 percent plagioclase, 20 percent opaque minerals, and 0 to 5 percent olivine).
2. Most of the igneous rocks fit a fractional-crystallization sequence, indicating that they represent either parts of a single intrusive sequence or samples of a number of similar sequences.
3. Breccias are of lower abundance at the Ocean of Storms than at the Sea of Tranquility, presumably because the regolith at the Ocean of Storms is less mature and thinner than that at the Sea of Tranquility.
4. A complex stratification exists in the lunar regolith that is presumed to be caused primarily by the superposition of ejecta blankets; at present, the possibility of a layer of volcanic ash cannot be discounted (for example, sample 12033).
5. The greater carbon content of the breccias and fines compared with that of the crystalline rocks is presumed to be caused largely by contributions of meteoritic material and solar wind.
6. The amount of noble gas of solar-wind origin is less in the Apollo 12 fines and breccias than in the Apollo 11 fines and breccias. The breccias contain less noble gas of solar-wind origin than the fines, indicating that the breccias were formed from fines that had less solar-wind noble gases than the fines presently at the surface.
7. The ${ }^{40} \mathrm{~K}-{ }^{40} \mathrm{Ar}$ measurements on the igneous rocks show that they crystallized 1.7 to 2.7 billion years ago. The presence of nuclides produced by cosmic rays show that the rocks have been within 1 meter of the lunar surface for 1 to 200 million years.
8. The Apollo 12 breccias and fines are similar chemically and contain only half the titanium content of the Apollo 11 fines. The composition of the crystalline rocks is distinct from that of the fines in that the rocks contain less nickel, potassium, rubidium, zirconium, uranium, and thorium.
9. The Apollo 12 samples contain less titanium, zirconium, potassium, and rubidium and more iron, magnesium, and nickel than the Apollo 11 samples. Systematic variations occur in the magnesium, nickel, and chromium content of the crystalline rocks; however, only small differences exist in the potassium and rubidium content.
10. Sample 12013 has a distinctive composition that is similar to that of a latestage basaltic differentiate. The sample contains larger amounts of silicon, potassium, rubidium, lead, zirconium, yttrium, ytterbium, uranium, thorium, and niobium than were found in any of the other Apollo 12 samples or in any of the Apollo 11 samples.

## APPENDIXA

## MINERALOGICAL/PETROLOGICAL DESCRIPTIONS

The descriptions presented in this appendix were compiled during the preliminary examination of the Apollo 12 lunar samples by members of the Preliminary Examination Team (PET) and the Lunar Field Geology Experiment Team. The name of the team member who compiled the information is given on the first line of each description. Selected photographs of most samples are included.

SAMPLE NO. 12001.0 WEIGHT 2216 GRAMS
FINE MATERIAL FROM SELECTED SAMPLE BOX HISTORY

THE SELECTED SAMPLE BOX WAS OPENED IN THE F201 VACUUM SYSTEM ON NOV. 26.1969. YITHIN an hour after epening the contents of the larger of the two teflon sample bags was opened. three large rocris vere removed. and the remaining fine MATERIAL WAS SCOOPED INTO A 1 CM. MESH SIEVE. LESS THAN 20 GRAMS OF CHIPS remained on the sieve. the rest. which passed through the sieve. was sealed IN A STAINLESS STEEL CAN AND COMPRISES SAMPLE 12001.

WHILE THIS MATERIAL WAS BEING SIEVED AND CANNED. THE F 201 CHAMBER PRESSURE YAS DECREASING FROM $5.3 \times 10-6$ TORR TO $4.2 \times 10-6$ TORR.
tHE CAN WAS RE-OPENED AT 0800 DEC 5 AND RE-CANNED IN FOUR SEPARATE CANS. THE PRESSURE DURING THIS OPERATION CHANGED AS SHOWN BELOW.

| 0800 | $3.4 \times 10-6$ |
| :--- | :--- |
| 0830 | $3.9 \times 10-5$ |
| 0900 | $5.0 \times 10-6$ |

F201 DESCRIPTION SUB NAPOLEONS HAT SHAPE CONCAVE ON BOTTOM. SUBANGULAR TO SUBROUNDED ON TOP VESICULAR MEDIUM GREY WITH WHITE PATCHY AREAS (PRESUMABLY THE MILKY FELDSPAR CRUSTY SURFACE SEEN ON APOLLO 11 CRYSTALLINE ROCKS
DUST COVERED BUT a FEW SMALL 2 TO 3 MM GLASSY PITS ARE VISIBLE AND ONE SMALL AREA SUGGESTS SPLASH. TEXTURE NOT VISIBLE. FRACTURES VISIBLE ON ONE END NO APPARENT RELATION TO ROCK SHAPE. THIS END SHATTERED AND FRIABLE. SOME vesicles are coalesced and appear vuggy. one at least. has reflecting crystal FACES. MOST VESICLES ARE IN THE RANGE OF 1 TO 4 MM. THE DUST IS STRONGLY ADHERENT TO ROCK AND RETAINS IMPRINTS OF TOOLS AND GLOVE ABRASIONS. FINE PINPOINT GLITTERS SUGGEST SOME
CRyStalline minerals are present in the dust. both the general appearance and all details that can be noted recall SPECIFICALLY THE COARSER GRAINED FACIES OF APOLLO 11 type A. we SEEM TO be DEALING WITH THE SAME OR VERY SIMILAR RECKS.

SAMPLENO. 12016.0 WEIGHT 2028.0 G DIMENSIONS \(7 \times 5 \times 4\) IN. HARMON F 20.1 DESCRIPTIOH
SHAPE IS SUBANGULAR WITH ROUNDED IRREGULAR SURFACES. COLOR IS A BROWNISH GREY WHERE DUST COVERED. A LIGHTER GREY ON FRESHER SURFACES (WHERE BRUSHED). THE rock has a rather salt and pepper texture and is definitely crystalline. the the rock is vesicular. but the density of vesicles on the surface appears low the rock also appears to have a thin surface crust typlcal of the apollo 11 CRYSTALLINE ROCKS ( a SHATTER CRUST ). THE DENSITY OF SURFACE PITS APPEARS LOW. BUT ARE VERY NICE IMPACT CRATERS (PITJ ABOUT 1.5 CM IN DIAMETER CAN BE SEEN ON ONE SIDE OF THE ROCK. THE THIN END OF THE ROCK alSO has a fRACTURE RUNNING DIAGONALLY ACROSS IT. THE BOTTOM (CONCAVE) SURFACE OF THE ROCK APPEARS TO BE more shattered than other surfaces. the Crystal grains are visible to the alded EYE. BUT NO MINERALOGY CAN BE DETERMINED. SOME GRAINS ARE LARGE ENOUGH TO make reflections visible by moving ones head back and forth. a medium grain CRYSTALLINE ROCK SLIGHT GLASS SPHERULES MAY ALSO BE PRESENT ON THE SURFACE.

Figure A-14. - Sample 12016.

SAMPLE NO. 12017.0 F201 DESCRIPTION D. ANDERSON/E. GIBSON
WEIGHT 53 GRAMS DIMENSIONS \(5 \times 3 \times 2.5 \mathrm{CM}\)
a COARSLY CRYSTALLINE MICROGABBRO TYPE ROCK WITH ABOUT 80 PERCENT OF ONE SIDE COVERED WITH A DARK SHINY GI.ASS LAYER. THE ROCK IS ROUGHLY PYRAMIDAL WITH VERY SHARE CORNERS AND FLAT SIDES. IT APPEARS HOLOCRYSTALLINE WITH THE FOLLOW ING MINERALOGY.

PLAGIOCLASE FELDSPAR (CLEAR TO TURBID WHITE) APPROXIMATELY 50 PERCENT PYROXENE. HONEY BROWN APPROXIMATELY 35 PERCENT (ONE CRYSTAL ABOUT 3MM LONG)
ILMENITE APPROXIMATEL.Y 10 PERCENT
OLIVINE LESS THAN 5 PERCENT.
there are no apparent lineations. vugs. vesicles or pits on rock. the dust COVER OBSCURES BASE ROCK BUT DOES NOT STICK TO GLASS EXCEPT FOR VERY THIN LAYER IN PLACES.
the outstanding feature is ihe large glassy patch. the glass has lustre of POLISHED MOLYBDENUM. IT APPEARS THINNEST AT POINTED END AND THICKEST R.T OPPOSITE END OF SIDE WITH GL_ASSY SURFACE. THE FCLLOWING FEATURES WERE OBSERVED ON THE GLASS.
1. NO IMPACT PITS ON SURFACE OF GLASS.
2. GLASS IS SOMEWHAT FRACTURED (ONLY A FEW LARGE FRACTURES).
3. BASE ROCK IS NO MORE ROUNDED UNDER GLASS THAN ELSEWHERE.
4. GLASS HAS NOT COMPLETELY UETTED ROCK BUT THERE ARE REGIONS WHERE BASE ROCK SHOYS THROUGH DIMPLES.
5. There are darker greenish brown elongate glass patches on surface of blacker glass. these are subparallel and appear to be eifidence of a later SPLASH. SOME OF THESE ARE 2 : MM LONG BUT MOST ARE LESS THAN 1 MM.
6. THERE ARE SHALLOW DEPRESSIONS IN GLASS SURFACE WHICH ARE LIGHTER COLORED. THESE ARE OVAL AND ARE ABOUT 2 TO 3 mm diameter.
7. at one end of the patch there are two places where the glass appears TO BE ALMOST 1 MM THICK \(\forall I T H\) A SHARP STRAIGHT EDGE AS IF FRACTURED OFF. ON one of these vertical surfaces several vesicles may be seen in the glass.
8. ALONG ONE EDGE OF THE GLASS SURFACE. THE GLASS AND PART OF BASE ROCK SEEM TO BE BROKEN a甘AY EXPOSING a BLEACHED SURFACE INDICATING THAT THE ORIGI NAL SURFACE OF THE ROCK HAS BEEN COVERED UP WITH GLASS.
9. a thick (I MMJ KNOB IN GLASS IN ONE PLACE MAY be a PIECE OF SOLID MATERIAL IN GLASS WHICH IS NOW COVERED UP.

Figure A-15. - Sample 12017.

SAMPLE NO. 12022 WEIGHT 1864.3 GR D. H. ANDERSON/VSA
F201 DESCRIPTION
MEDIUM GRAINED CRYSTALLINE ROCK (GRAIN SIZE APPROXIMATELY 0.1 MM) WITH NUMEROUS VISIBLE SURFACE PITS. PITS RANGE IN SIZE FROM 2 MM TO O.1 MM WITH A PIT DENSITY OF TVO PITS PER SQUARE MILLIMETER. THE PITS ARE ALL GLASS LINED. THE OUTER MOST MILLIMETER Or THE ROCK APPEARS TO BE UNIFORMLY MORE WHITE THAN THE INTERIOR OF THE. ROCK. THE INTERIOR IS APPARENTLY OF A DARK GRANULAR TEXTURE. the small portion visible appears sugary. one corner near the apex of the rock appears to have been broken off. but a very few glassy pits on this supface indiEate it may have happened some time ago. the overall surface of the rock IS FAIRIY SMOOTH WITH FEW PLACES CLEAN ENOUGH TO SHOW The true SURFace. the ROCK IS APPARENTLY RATHER hard because the tool in the vacuum chamber have left metal scrappings on the sharp corners of the rock. there is no indication of LAYERING OR PREFERRED FRACTURE. PLANS FPOM THE POSITION OBSERVED.
THE COLOR IS DARK GREY OVERALL WITH LIGHT PATCHES SHOWING THROUGH THE DUST. no mode can be determined yet. but the dark minerals appear to be more abundant than the light. a few greenish grains colivine appear on the surface. this VIEW IS with the rock in the same position as in the photos. COLOR. SPECKLED LIGHT GRAY WITH A BROWNISH GREENISH CAST. TEXTURE, VERY VUGGY. COALESCED VUGS AS MUCH AS 1 CM IN DIAMETER. THUS MAKING THIS SPECIMEN EXCELLENT FOR CFYSTALLINE STUDY. HOLOCRYSTALLINE GRANULAR. abundance of fractures is mincir.

SAMPLE NO. 12022.0 VEIGHT 1864.3 GR DIMENSIONS 14 CM X 9.5 CM X 7 CM HARMON THIS ROCK HAS a blocky shape (that of an IRREGULAR pyramid. the COLOR IS a MEDIUM GREY WHERE THE SURFACE IS COVERED WITH DUST. BUT AREAS OF A LIGHTER GREY and yhite are scattered over the surface of the rock where the dust is not pRESENT AND DARKER Where fresh SURfaces are exposed belot the surface of the ROCK. THE ROCK IS CRYSTALLINE AND OF A MEDIUM FINE GRAIN SIZE. THE ROCK SHOWS NO FRACTURING TO THE UNAIDED EYE OR THROUGH THE STEREO MICROSCOPE EXCEPT THAT ONE CORNER OF THE ROCK HAS BEEN GROKEN OFF. NUMEROUS MICROMETEORITE IMPACT PITS are present on all surfaces of the rock. the fractured surface having feber than OTher surfaces. these pits are almost alyays glass lined. but some glass was observed on the surface of the rock. no mineralogy is readily identifiable by binocular microscope examination of the sample other than perhaps a felospar (WHITE LATH SHAPED MINERAL). SOME OLIVINE (LIGHT GREEN. EQUANT GRAINS). AND and a mineral with a grey metal.lic luster. In one spot on the SURFACE AN EQUANT BROWN GRAIN ( \(1 / 4\) MM) IS PRESENT ALL ALONE ON THE SURFACE OF the rock. IT appears to be glass. but may be the honey brown mineral seen in SOME APOLLO 11 ROCKS. THE SURFACE OF THE ROCK TO DEPTH OF ABOUT 1 MILLIMETER appears to be a shatter crust as the areas where white and light appear c areas OF NO DUSTJ. THESE GRAINS ARE HIGHLY BROKEN UP. THE INTERIOR OF THE ROCK GENERALLY APPEARS TO BE QUITE DARK BELOW THIS SHATTER CRUST / A DARK GREY/GREEN.

the folloying experiment vas conducted on this sample
total carbon analysis

Four drive-tube core samples were collected from three localities and returned by the Apollo 12 crew. The location of the core-tube samples is shown in figure 3. The second and third core tubes were screwed together in a successful attempt to penetrate a light-colored layer underneath a dark layer. The first three core tubes were opened, described, and dissected to provide samples for biological and physical analyses. The fourth core tube remains in storage.

The Apollo 12 core samples differ from those collected at the Sea of Tranquility in that they have easily recognizable stratigraphy and two coherent crustlike layers; otherwise, they resemble the Apollo 11 cores in their dominantly fine-grained textures and loose consistency; in their restricted range of medium-gray colors and fresh unoxidized appearance; and in their abundance of glass, including some spherules. As in the case of sediment from the Apollo 11 cores, dissection of the Apollo 12 cores produced weakly coherent ephemeral structures ranging from fine subrounded crumblike units 1 to 2 millimeters in diameter to subangular blocky or occasional angular units with maximum dimensions of 5 millimeters. The coherence throughout most of the sediment was sufficiently adequate to permit careful dissection of small 1-centimeterhigh vertical faces before slumping occurred.

All cores opened were broken by fine fracture planes, usually transverse to the core tube. Where such fractures coincide with changes in the character of the sediment, they are interpreted as bedding planes. Other more complex fracture zones not coinciding with morphological changes may be shear fractures produced when the drive tubes were rotated as the samples were collected.

The core collected on the first EVA is 19.3 centimeters long and is uniformly medium to dark gray. The stratification is shown clearly in the abrupt change in the abundance of rock fragments and glass particles larger than 1 millimeter below a transverse fracture at a depth of 5.9 centimeters. This stratification also is reflected by changes in the mean grain size with depth (fig. A-21). Because of the coherence of the fine particles, reliable mechanical analyses below 0.062 to 0.031 millimeter could not be obtained. Coarse material larger than 2.00 millimeters could not be analyzed because of the limited sample size.

The three mechanical analyses (fig. A-21) of the first core are similar to those of the Apollo 11 cores. The slope of the cumulative curves, and thus the sorting, is very similar for all three samples; however, successively deeper samples are progressively coarser. The median grain size changes from 0.062 millimeter for the surface sample to 0.074 millimeter for the middle sample and 0.11 millimeter for the deepest sample.

Stratification and morphological changes are most evident in the double-tube core sample collected at Halo Crater. The entire lower tube ( 32 centimeters) and 9.3 centimeters of the upper tube were filled with sediment. At least 10 layers or horizons have been recognized. The most distinctive of these units is a coarse layer of angular rock fragments, minerals, and glass that is comprised mostly of olivine grains and olivine-rich gabbros. The fourth mechanical analysis (fig. A-21) is of this coarse layer. The slope of the cumulative grain-size curve, and thus the sorting, is similar
to the fines material but displaces markedly towards the coarse end of the graph. Extrapolating to the 50 percentile, the median grain size is approximately 4. 9 millimeters.

Figure A-21. - Mechanical analyses of first core tube and of coarse layer of double core tube.

The sharp contact with the fines material above and below the coarse layer and the lack of fines and the log-normal distribution of the coarse layer suggest that the layer is of primary-impact origin. The gradual increase in grain size with depth shown by the three analyses from the first core also suggests that the grain size of the debris has decreased because of reworking, probably by successive impacts.

Other units found in the deep core include a fine-textured zone of lighter mediumgray material, a żone of mixed incoherent light- and medium-gray sediments, and, at the base of the core, a layer of much lighter gray material. This lowermost layer is similar in appearance to sample 12033.

Both the coarse layer and a medium-gray 2-centimeter-thick layer (collected just below the surface at the Halo Crater site) have a friable consistency unlike any Apollo 11 core materials. Coarse particles larger than 1 millimeter in both layers may be strongly bonded aggregates that are indigenous to the layers rather than admixed fragments.

The first division of the Apollo 12 core tubes is shown in table A-I. Core-tube samples 12028 and 12026 are shown in figure A-22; core-tube samples 12025 and 12028 are shown in figure A-23. An X-ray radiograph of core-tube sample 12027 is shown in figure A-24.

Figure A-25. - Sample 12030.

SAMPLENO. 12031 VEIGHT 185 G DIMENSIONS \(5.5 \times 5 \times 5\) CM HEIKEN BLOCKY. EQUANT SUBANGULAR ROCK. BROWNISH GRAY. COARSE GRAINED HOLOCRYSTALLINE TEXTURE. DISTINCT ORIENTATION OF FELDSPAR LATHS. POSSIBLY FLOW STRUCTURE SMALL IRREGULAR FRACTURE WHERE PIECES ARE ABOUT TO SPALL OFF ON BOTTOM SIDE. THERE IS a SMall SYSTEM OF axIALITIC STRUCTURE CONSISTING OF abundant feld PYROXENE QUITE DIFFERENT FROM ORIENTATION ON TOP. NO VESICLES OR VUGS. A FEW TINY SURFACE PITS. LINED WITH BLACK GLASS LESS THAN 1/2 MM IN DIAMETER. ANY SURFACE features that may have been present have probably crumbled off in TRANSIT. ONE VUG APPROXIMATELY 1 MM VIDE SLIGHTLY OFF CENTERED ACROSS THE ROCK LINED WITH GOOD FELDSPAR AND PYROXENE CRYSTALS GROWING PARALLEL TO THE WALL. THE ORIENTED FELDSPAR CRYSTALS INTERSECT THIS VUG AT APPROXIMATELY 30 DEGREES. FELDSPAR. MILKY WHITE LATHS UP TO 12 MM LONG. THEY ARE PRETTY BADLY SHATTERED. many inclusions of the dark mineral into the felospar approximately 65 percent OF ROCK.
PYFOXENE. REDDISH BROWN. AN TO SUBHEDRAL CRYSTALS. ELONGATE AND ENCLOSE OLIVINE CORES UP TO B MM LONG AND 12 MM WIDE. APPROXIMATELY 15 PERCENT OF ROCK. APPROXIMATELY 1 MM DIAMETER OCCUR IN CLUSTERS ALWAYS ASSOCIATED WITH PYROXENE. OLIVINE 10 PERCENT. ANHEDRAL CRYSTALS MOSTLY EOUANT. SOME ELGNGATE. EQUANT ILMENITE 10 PERCENT. BLADE LIKE CRYSTALS UP TO 3 MM LONG. SOME CONCAVE OF ILMENITE CLOSE TO VUGS. also some held as inclusions in feldspar. COARSE GRAINED DIABASE.

SAMPLE NO. 12031 WEIGHT 185.0 DIMENSIONS \(5 \times 5 \times 4.5\) BAG 30 CHAO HOLOCRYSTALLINE. SPECIILED GRAY. COARSE GRAINED CRYSTALLINE ROCK. ROUGHLY CUBIC SHAPED. GLASS LINED PIT SURROUNDED BY MILKY WHITE HALO. PROBABLY CRUSHED FELDSPAR OCCUR ON SURFACE VITH PATCHES OF DUST. (PITS ARE APPROXIMATELY. 7 MM). TEXTURE. SLIGHTIY VUGGY. VUGS APPROXIMATELY. 7 MM DIAMETER. HIDELY SCATTERED. TEXTURE IS CHARACTERIZED BY LONG RADIATING CRYSTALS PRINCIPALLY PYROXENE WITH MIXTURES OF FELDSPAR AND PYROXENE FILLING THE INTERSTICES BETWEEN LONG BLADED CRYSTALS OPHYTIC.
APPROXIMATELY 35 PERCENT MINERAL PIGEONITIC CLINOPYROXENE. OCCURS AS ZONED LONG PRISMATIC CRYSTALS AS MUCH AS 2.5 CM LONG AND 1.5 MM VIDE. PRISMS. THESE PRISMS CONSIST OF A CORE OF UHITE PLAGI OCLASE FELDSPAR WITH RIM OF GREEN YELLOW PIGEONITE WHICH IS BORDERED BY DARK CINNAMON AUGITIC CLINOPYROXENE. THESE PRISMS SHOH DISTINCT PARTING AT STEEP ANGLES TO THE ELONGATION.
THE INTERSTICIAL MINS CONSIST OF CLEAR TO WHITE PLAGIOCLASE (3O PERCENT) WITH VITREOUS LUSTER. INTERGROHN WITH CINNAMON BROWN ALGITE CLINOPYROXENE APPROXIMATELY 20 PERCENT.
ILMENITE OCCURS AS BLACK GRAINS APPROXIMATELY. 7 MM ACROSS WITH VERY METALLIC LUSTER. ASSOCIATED WITH INTERSTICIAL FELDSPAR AND CLINOPYROXENE USUAILY IN PLATY HABITS APPROXIMATELY 10 PERCENT.
MODAL COMPOSITION SHOULD BE ESTIMATED AND CHECKED BY T.S.
LIGHT BUFF COLORED FINE GRAIN MINERAL WHICH COULD BE TRIDYMITE.
SOME EQUIGRANULAR YELLOW GRAINS SHOULD BE CHECKED FOR OLIVINE WITH AT.S. FRACTURE. SEVERAL IRREGULAR COARSE FRACTURES CUT THRU THE ROCK GIVING IT A FRIABLE APPEARANCE.
ShOCK. EXCEPT LOCALLY ON THE SURFACE WHERE MILKY WHITE PATCHES OF CRUSHED feldspar occur there is weak megascopic evidence of shock present by the fine FRACTURING OF MOST OF THE MINS PRESENT.
CAN BE REFERRED TO AS A GABBRO WITH CHARACTERISTIC BLADED AND FEATHERY COARSE PIGEONITIC CLINOPYROXENE.
COLOR. SPECKLED LIGHT GRAY WITH A BROWNISH GREENISH CAST.
TEXTURE - VERY VUGGY HOLOCRYSTALLINE GRANULAR ROCK
COALESCED VUGS AS MUCH AS I CM IN DIAMETER.

Figure A-26. - Sample 12031.

SAMPLE NO. 12032 VEIGHT 310.59 G (+ BAG). FINES. \& D. HEIKEN MEDIUM DARK GRAY. POORLY SORTED. MOSTLY SANDY SILT SIZE MATERIAL. SOME ANGULAR FRAGMENTS UP TO 4 MM. LARGER FRAGMENTS INCLUDE FLAT PIECES OF GLASS (VESICULAR). POSSIBLY SPATTER. FINE GRAINED MATERIAL INCLUDES GRAINS OF OLIVINE. FELDSPAR. PYROXENE AND GLASS AND BRECCIA.

\section*{THE FOLLCWING EXPERIMENT WAS CONDUCTED ON THIS SAMPLE}

TOTAL CARBON ANALYSIS

SAMPLE NO. 12033 FINES SD HEIKEN
FINE GRAINED MATERIAL. MEDIUM GRAY (NS). MUCH LIGHTER THAN FINE GRAINED SOIL
FROM ELSEWHERE AT THE SURVEYOR SITE. GRAIN SIZE. PEBBLE BEARING. SAND SILT. there are a number of 1 mm to 10 mm LONG angular and subangular rock fragments IN THE SOIL SAMPLE (IDENTIFICATION NOT MADE DUE TO DUST COVERINGJ. MOST FRAGMENTS APPEAR TO BE LESS THAN O. 05 IMM IN DIAMETER. MODERATELY SORTED. APPEAR TO BE MOSTLY SMALL FELDSPAR AND PYROXENE CRYSTALS WITH MINOR AMOUNT OF GLASS. are some cless than 1 percent 1 mm diameter olivine crystals. SEVERAL OF THE LARGER FRAGMENTS PULLED OUT. ARE TWISTED. PUMICEOUS GLASS FRAGMENTS. DARK BROWN GLASS.

SAMPLE NO. 12033 HEIKEN
A PINCH STUDIED IN A DROP OF 1.515 R.I. IMMERSION OIL. IS A BIMODAL DISTRIBUTION AT THIS SCALE. ANIGULAR FRAGMENTS OF DIAMETER OF 0.17 MM. ( 20 PERCENT) AND FRAGMENTS LESS THAN 0.02 MM.
THE COARSER MODE CONSISTG OF SHARP. ANGULAR SHARD-LIKE PIECES OF DARK RED-BROWN GLASS. THE GLASS CONTAINS MICROPHENOCRYSTS OF OLIVINE (OUESTION) AND MICROLETES. EMPHASIZING SOME FLOW STRUCTURE.
THE FINER MODE CONSISTS OF ANGULAR. EUHEDRAL TO SUBHEDRAL CRYSTALS. 0. 025 TO 0.002 MM IN DIAMEIER. IT CONSISTS OF APPROXIMATELY.-
1. 75 PERCENT FELDSFAR
2. 15 PERCENT OLIVINE AND PYROXENE
3. 10 PERCENT DARK BIZOWN GLASS AND OPAOUES.

GLASS FRAGMENTS ARE SUBRCIUNDED TO ANGULAR (ROUNDED ONES REWORKED OR ERODED IN AN ERUPTION CLOUDJ. ONE GLASS SPHERE WAS SEEN.
IS SIMILAR IN MANY RESPECTS TO HYALOCLASTIC GLASSES.
COARSEST FRACTION STUDIED EARLIER IN BIO PREP. CONSISTS OF 1 MM DIAMETER
OLIVINE CRYSTALS AND MANY TWISTED. PUMICEOUS DARK BROWN GLASS FRAGMENTS. CONTAIN ELONGATE. PIPE-LIKE VESICLES AND SHOW ABUNDANT FLOW FEATURES. DUE TO LACK OF ROCK FRAGMENTS. SHOCKED CRYSTALS AND TO THE PRESENCE OF PUMICEOUS AND SHARD-LIKE FRAGMENTS OF BASALTIC GLASS. THE SAMPLE APPEARS TO BE A CRYSTALVITRIC ASH OF VOLCANIC Ofigin. this sample may be the same as the white layer in the bottom of the core: taken at halo crater.
the following experiment was conducted on this sample
E-SPEC ANALYSIS
TOTAL CARBON ANALYSIS

SAMPLE 12034.0 DOCUMENTED SAMPLE 6 D DECEMBER 4. 1969 W. R. GREENWOOD MEDIUM LIGHT GRAY MATRIX (A) OF FINE GRAINED MATERIAL INCLUDES CRYSTAL FRAG MENTS AND FRAGMENTS OF A NUMBER OF ROCK TYPES.
there is a faint preferred shape orientation defined by the elongation of two LARGE ROCK INCLUSIONS (UNIT B AND C).
MATRIX (A) INCLUDES CRYSTAL FRAGMENTS OF BLACK PYROXENE UP TO 7 MM WHICH ARE highly angular. the larger pyroxene crystal fragments appear to have a much PREFERRED SHAPE ORIENTATION PARALLEL TO THE ELONGATION OF UNITS (B) AND (C). PYROXENE CRYSTALS COMPRISE 70 PERCENT OF THE CRYSTAL FRAGMENTS LARGER THAN 。 2 MM IN MATRIX (A). MILKY WHITE FELDSPAR MAKES UP THE REMAINING 30 PERCENT. IN THE SMALLER SIZES LESS THAN . 2 mM FELDSPAR APPEARS TO MAKE UP a LARGER percentage of the crystal fragments. about 10 percent of the rock is made up OF ROCK FRAGMENTS. ABOUT 20 PERCENT OF THE ROCK IS CRYSTAL FRAGMENTS GREATER THAN . 2 MM.
UNIT (B) IS LIGHT GRAY WITH SHARP BUT SOMEWHAT SOFTENED BOUNDARIES WITH MATRIX (A). UNIT (B) HAS SOMEWHAT IRREGULAR PANCAKE SHApE. UNIT (B) APPEARS TO BE COMPOSED OF WHITE FELDSPAR CRYSTAL FRAGMENTS LESS THAN . 2 MM AND BLACK PYROXENE CRYSTAL FRAGMENTS UP TO 2.0 MM IN SIZE. THE PYROXENE CRYSTALS ARE ANGULAR. UNIT (B) APPEARS TO BE A WELDED FRAGMENTAL ROCK. THERE IS SUGGESTION OF elongation of plagioclase shards near and parallel to the elongate side cf UNIT (B). UNIT (B) IS LOCATED AT ONE EDGE OF THE FRESH FACE OF THE ROCK AND IS 30 MM X 8 MM IN SECTIONS. WITH A FLATTENED PYRAMID SHAPE WITH ROUNDED CORNERS AND SOMEWHAT !RREGILLAR BOUNDARIES . ¿HISPS OF THE SAME UNIT ARE FOUND NEAR AND PARALLEL TO UNIT (B) IN MATRIX (A). UN\}T (C) IS SLIGHTLY LiGHTER GRÁY THAN MATRIX (A) BUT CONSIDERABLY DARKER THAN UNIT (B). UNIT (C) IS COMPOSED OF CRYSTAL FRAGMENTS (ABOUT 40 PERCENT) AND A MEDIUM GRAY MATRIX. THERE IS A IRREGULAR SHARP BOUNDARY BETWEEN UNIT (CJ AND THE MATRIX (A). UNIT (C) IS LOCATED NEAR THE MIDDLE OF THE FRESH FACE. ONE FRAGMENT IS ABOUT 20 MM X 7 MM IN SECTIONS. A SMALLER FRAGMENT IS 10 MM X 5 MM on the same plane as fragment (i). these tho fragments are separated by a NARROW (G MM) SIDE OF MATR!X (A).
UNIT (C) CRYSTAL FRAGMENTS ARE WHITE PLAGIOCLASE UP TO 1 MM. 90 PERCENT OF TOTAL FRAGMENTS. 10 PERCENT OF THE FRAGMENTS ARE BLACK PYROXENE UP TO 1 MM. UNIT (C) MAY BE A SHOCKED AND PARTIALLY MELTED ROCK ON AN OLDER BRECCIA. adDitional smaller fragments of unit (C) are located near the layer fragments. THERE ARE TWO INTERSECTING FRACTURE SETS. ORIENTATION OF THE INCLUDED ROCK FRAGMENTS. THE FRACTURES ARE CLOSELY SPACED AND LOCALLY PRGDUCE A STRONG CLEAVAGE . THE FRACTURE SETS INTERSECT at about 40 DEGREES. ONE OF THE FRACTURE PLANES IS PARALLEL OR NEARLY SO TO THE PREFERRED ORIENTATION OF INCLUDED ROCK FRAGMENTS IN THE ROCK.
THE ROCK IS NOT FRIABLE OR FRAGILE. NO GLASS BALLS OR FRAGMENTS WERE SEEN megascopically. the rock is not megascopically vesicular. one of the broken faces has a dark lineated surface that may be a relic of a slickensided SURFACE.
SOME OLIVINE CRYSTALS LESS THAN 5 PERCENT OF TOTAL CRYSTAL FRAGMENTS IN MATRIX (A). ONE VERY SMALL FRAGMENT APPROXIMATELY 1 MM DIAMETER IS COMPOSED OF BLACK GLASS. SHATTERED OLIVINE. AND MILKY TO VITREOUS GLASS PLAGIOCLASE. THE FRAGMENT APPEARS TO BE PARTIALLY SHOCK MELTED.
UNIT (B) HAS A STREAMED OUT END BY FLOWING AND IN MATRIX IS a LINE PARALLEL TO THE BOUNDARY PRODUCED BY FLOWING. THERE IS PARTING PARALLEL TO THIS FLOW. IN UNIT (B). ONE OF THE SHATTERED FELDSPAR HAS a CORE OF TRANLUSCENT plagioclase NO VITREOUS MATRIX WAS SEEN IN MATRIX (A) AT HIGHEST MAG APPROXIMATELY ioox. THE ROUNDED SIDE OF THE ROCK APPEARS TO HAVE A SUBVITREOUS SKIN OF ABOUT 1 TO 3 MM THICK (MEDIUM DARK GRAY) VESICULAR PARTIALLY CRYSTALLINE GLASS. THE GLASSY MATERIAL HAS A COATING OF LIGHT GRAY SOIL WHICH APPEARS BONDED ON. WHEN This Sample was first returned the coating was about 1 to 3 mm thick. now ABOUT \(1 / 2\) TO 1 MM OF DUST COATS THIS SIDE. IT IS VERY DIFFICULT TO REMOVE.

Figure A-27. - Sample 12034.
```

DUST IS MORE EASILY REMOVED FROM THE FRESH BROKEN SIDES. THE GLASS COATING FOLLOWS THE ROUNDED TOPOGRAPHY OF THE ROCK EXTENDING DO甘N INTO FRACTURES. vesicles in the glass are elongated parallel to the surface of the rock. after FORMATION OF THIS ROCK BY WELDING OR SOME OTHER PROCESS IT WAS BLASTED TO THE surface (developing the cleavages). on the surface the rock was rounded. sub SEQUENTLY IT WAS PARTIALLY COATED WITH MOLTEN ROCK MATERIAL. THE ROCK WAS SUBSEQUENTLY BROKEN AND DEPOSITED AT THAT TIME OR LATER IN THE LIGHT GRAY DUST LAYER.
SAMPLE NO. 12034 CHIP $1.5 \times 0.75 \times 0.5 \mathrm{CM}$ ROBIN BRETT
BRECCIA. LIGHT GRAY IN COLOR COMPARED TO ALL APOLLO 11 bRECCIAS. GRAIN SIZE OF FINE MATRIX ABOUT 0.I MM. ROCK CONSISTS OF 25 PERCENT FRAGMENTS UP TO I MM. SHAPE OF ROCK NO CONSEQUENCE AS IT IS A CHIP WITH NO OUTSIDE SURFACE. A FEW SMALL FRACTURES PRESENT. CLASSED IN ORDER OF ABUNDANCE ARE.

1. DARK ANGULAR GLASS FRAGMENTS SHOWING RARE CLASTS TO 0.2 MM OF GLASS OF DIFFERENT COMPOSITION. SHOCKED FELDSPAR. PYROXENE. RARE VESICLES IN GLASS.
2. SHOCKED ANGULAR TO SUBROUNDED PLAGIOCLASE GRAINS FROM MILKY WHITE TO VITREOUS.
3. BUFF TO CINNAMON BROWN ANGULAR PYROXENE GRAINS.
4. GREEN ANGULAR OLIVINE GRAINS. NO SPHERULES EVIDENT. GRAIN MOUNT OF MATRIX SHOWS FOLLOWING ANGULAR GRAINS (IN ORDER OF ABUNDANCE)
5. PLAGIOCLASE. MOSTLY LIGHTLY SHOCKED UP TO THE THETAMORPHIC. SOME POLYSYNTHETIC TWINS.
6. PYROXENE . MAINLY SHOCKED.
7. ANGULAR OPAQUE GLASS FRAGMENTS.
8. ANGULAR ILMENITE.
high plagioclase content explains light gray color. ROCK NAME. MICROBRECCIA.
THE FOLLOWING EXPERIMENT WAS CONDUCTED ON THIS SAMPLE
A-A CHEMICAL ANALYSIS
E-SPEC ANALYSIS
RARE GAS ANALYSIS
TOTAL CARBON ANALYSIS
```

SAMPLE NO. 12035 DIMENSIONS \(5 \times 4 \times 1.5 \mathrm{CM}\) HONES
SHAPE. TRIAXIAL ELLIPSOID. NOW FRAGMENTED INTO 5 LARGE PIECES AND FINES. SIZE OF FRAGMENTS. \(1.5 \times 2 \times 4.2 \times 1.5 \times 3.1 .5 \times 1.5 \times 1.5 .2 \times 2 \times 1\). \(1 \times 1 \times 0.5\) CM.
COLOR. LIGHT OLIVE GRAY.
TEXTURE. COARSE. CUMULAR. HYPIDIOMORPHIC.
FABRIC. VUGGY. VUGS ARE IRREGULAR 4 MM OR MORE. NO ORIENTATION OR CLUSTERS. FRACTURES ARE THRU GOING AND ABUNDANT. THE ROCK IS FRIABLE. NO OBSERVED ORIENTATION OF FRACTURES. SURFACE TEXTURES ALL APPEAR TO BE FRESH FRACTURED SURFACES.

OLIVINE 40 PERCENT EUHEDRAL. EQUANT. APPROXIMATELY 1 MM MEAN DIAMETER. CLEAR. GREEN. CONTAIN OPAQUE INCLUSIONS.

PLAGIOCLASE 45 PERCENT GLASSY. THINNED. PRISMATIC. INTERSTITIAL WITH OLIVINE INTERGROWN VITH PYROXENE APPROXIMATELY 1 MM MEAN SIZE 2 TO I RATIO AVERAGE \(1 \times 1 / 2\) MM.

PYROXENE 15 PERCENT PRISMATIC MAXIMUM 2.0 MM MOST . 3 MM LONG. EQUANT EXCEPT IN VUGS ASICULAR IN RATIO OF 5 TO 1. HONEY BROWN COLOR.

OPAQUES LESS THAN 1 PERCENT. BLADED. LUSTROUS. TEND TO CONC. AROUND vUGS. BUT ARE PRESENT AS INCLUSIONS IN OLIVINE.
olivine is present in vugs. sequence of crystallization is opaques. olivine. pLAGIOCLASE. PYROXENE ALL FERSIST IN TERMINAL CRYSTALLIZATION. NO ALTERATION OBSERVED.
ROCK NAME TROCTOLITE

F'igure A-28. - Sample 12035.

SAMPLE NO. 12036 WEIGHT 75 G DIMENSIONS \(6 \times 3.5 \times 2.3\) CM CHAO FROM BAG 8 D.
MINERALOGY. THIS ROCK CONSISTS OF ABUNDANT GRAYISH YELLOW EUHEDRAL TO GRANULAR CRYSTALS OF OLIVINE IN A MATRIX OF INTERGROWN FELDSPAR AND BROWN PYROXENE AND some octahedral spinel.
1. OLIVINE. 40 PERCENT. FORMS EUHEDRAL CRYSTALS UP TO 2 TO 2 MM ACROSS WITH WELL DEVELOPED CRYSTALLINE FACES PARTICULARLY THOSE IN THE VUGS. THESE CRYSTALS USUALLY CONTAIN DARK BLACK REFLECTING CRYSTALS SOME OF WHICH SHOW OCTAHEDRAL HABIT. SPINEL. FROM CHROMITE OR MAGNETITE.
2. PLAGIOCLASE FELDSPAR. 40 PERCENT. OCCURS AS GRANULAR IRREGULAR PATCHES. CLOSELY INTERGROWN WITH OLIVINE AND BROWN PYROXENE UP TO 2.5 MM AVERAGING APPROXIMATELY 1.O MM.
3. CINNAMON BROWN CLINOPYROXENE. 15 PERCENT. PROBALBY PIGEONITIC. FORMS STUBBY PRISMATIC CRYSTALS NEAR VUGS OR LARGE CRYSTALS THAT ARE POIKILITIC. SUGGESTING LATE CRYSTALIZATION. ALSO OCCURS AS FINE GRAINS INTERGROWN WITH FELDSPARS.
4. OPAQUE MINERALS APPROXIMATELY 5 PERCENT. SOME DARK MINERALS WITH metallic luster, usually fine grained cless than i mm may be ilmenite cvery SMALL AMOUNTJ HIDE SPREAD ARE SMALL GRAINS OF EQUIGRANULAR OPAOUE. Which are probably same as octahedpal crystals as of spinel grained group. SHOCK. NO MEGASCOPIC CLEAR EVIDENCE OF SHOCK. ROCK NAME. A GABBRO OR A PIGEONITIC TROCTOLITE.

SAMPLENO. 12036 WEIGHT 75 G DIMENSIONS \(6 \times 3.5 \times 3.5\) HEIKEN ELONGATE. VERY IRREGULAR SHAPE. SUBANGULAR. MEDIUM GRAINED HOLOCRYSTALLINE ROCK. EXTREMELY VUGGY. VUGS MAKE UP APPROXIMATELY IS PERCENT OF VOLUME OF ROCK. VERY CRUDE ORIENTATION OF VUGS PARALLEL TO LONG AXIS OF ROCK. NEAR EDGES. VUGS ARE FROM 0.5 TO 4.0 MM IN DIAMETER . SOME FRACTURES EXTENDING OUT FROM VUGS. ON OTHER SIDE IS ONE GOOD FLAT SURFACE (FRACTUREDJ AND HAS DUST AOHERING TO IT. NO VISIBLE PITS OR SPLASHES.
CLEAR GREENISH YELLOW OLIVINE SUB TO EUHEDRAL CRYSTALS 1 TO 3 MM DIAMETER. APPROXIMATELY 40 PERCENT.
FELDSPAR SUB TO EUHEDRAL CRYSTALS FROM 0.5 TO 2.0 MM LONG. MOST ARE COLORLESS EXCELLENT TWINNING APPROXIMATELY 25 PERCENT.
PYROXENE. REDDISH BROWN TO DARK REDDISH BROWN APPROXIMATELY 25 PERCENT. FROM 2 TO 5 MM SUBHEDRAL CRYSTALS PRISMATIC CRYSTALS. BLADED ILMENITE CRYSTALS UP TO 3 MM LONG 10 PERCENT. IN VUGS CRYSTALS ARE EXCELLENT WITH GOOD CRYSTAL FACES.

12 D FINES. DARK GRAY. MODERATELY SORTED. FINE SAND SIZED. A LOT OF FELDSPAR GRAINS AND SOME OLIVINE AND SOME GLASS. NO FRAGMENTS GREATER THAN 0.2 MM VISIBLE IN THIS PARTICULAR SPLIT. E.

EXTREMELY COHESIVE. WHEN COMPACTED A VERTICAL WALL CUT INTO IT STANDS VERY EASILY. WHEN TOSSED ABOUT LOOSELY IT TENDS TO CLUMP IN CLUMFS APPROXIMATELY 1.0 MM IN DIAMETER.
the following experiment was conducted on this sample
total carbon analysis

SAMPLE NO. 12043.0 HEIKEN
SUBROUNDED. OVOID ROCK. ONE END HAS ANGULAR FRESHLY FRACTURED SURFACE. BLUISH GRAY. MEDIUM GRAINED HOLOCRYSTALLINE, VARIOLYTIC VESICULAR WITH SPHERICAL VESICLES UP TO 2 MM IN DIAMETER. VESICLES ARE APPROXIMATELY 10 PERCENT OF VOLUME. NO ORIENTATION OF VESICLES. ON ANGULAR SIDE ARE a NUMBER OF SMALL FRACTURES parallel to surface. a half mm yide impact pit every 25 mm. 4 Pits less than 0.2 mM IN DIAMETER IN THE SAME AREA. THE PITS ARE LINED WITH VERY THIN. TRANSPARENT LAYER OF GLASS UITH A BUBBLY SURFACE. SOME CRYSTALS CAN BE SEEN THROUGH GLASS. MANY PIT LININGS ARE RAISED SLIGHTLY ABOVE THE ROCK. AS IF THE ROCK AROUND HAS BEEN ERODED AWAY. EACH HAS A 0.4 MM WIDE UHITE COROINA OF CRUSHED MINERALS. ONE CORNER APPROXIMATELY \(21 / 2 \times 2\) CM. IS COVERED WITH IRREGULAR SPLASHES OF BLACK GLASS LESS THAN O.1 MM THICK. CONTAINS SEVERAL blobs of glass which have been welded to surface. one blob is highly vesicular. VESICLES BEING APPROXIMATELY. 05 MM IN DIAMETER. MUCH OF THE THIN GLASSY SURFACE IS IRREGULAR DUE TO BROKEN COALESCING VESICLES. SOME OF THIS GLASS IS ALSO SLIGHTLY RaISED above the surface of the rock. one large vesicle is partly COATED WITH GLASS SPLASH.

MINERAL NO. 1 MILKY WHITE FELDSPAR. EXHIBITS ALBITE TWINNING. CRYSTALS VARY FROM 0.5 TO 2. 0 MM LONG MOSTLY THIN LATHS 45 PERCENT.

MINERAL NO. 2 GROWING PARALLEL TO FELDSPAR ARE REDDISH BROWN PYROXENE 0.5 TO 2.0 MM LONG. APPROXIMATELY 40 PERCENT.

MINERAL NO. 3 EQUANT 1 MM DIAMETER GRAINS OF PALE GREEN OLIVINE. APPROXIMATELY 5 PERCENT.
mineral no. 4 anhedral. equant crystals of ilmenite usually less than 1 MM LONG. 10 PERCENT.
SOME VESICLES HAVE EUHEDRAL CRYSTALS OF PYROXENE AND FELDSPAR GROWING SUBparallel to walls. variolytic diabase.

SAMPLE NO. 12043.0 DIMENSIONS 3.5 X 4.5 X 2.5 CM GREENWOOD MEDIUM GRAY WITH LIGHT GRAY AROUND PITS. WELL ROUNDED. SOMEWHAT OF A LEVER SHAPE THAT HAS BEEN BROKEN ON MOON. THE OLD SURFACE IS PARTIALLY COATED WITH BLACK GLASS SPLASHES. NEAR BLACK GLASS SPLASHES AND RELATED IS A DULL BLACK coating that chipped abay. the glass coating is on the oldest surface and follows the topography around the corner of the lense. the old surface is VERY DENSELY PITTED WITH IMPACT PITS HAVING GLASS LININGS AND BRIGHT HALOES. the broken surface also has pits with Glass linings but they are not so NUMEROUS. THE BROKEN SURFACE IS SUBANGULAR TO SUBROUNDED. THE CORNER THAT wAS FRESHLY CHIPPED IN LABORATORY IS DARK GRAY AND SHOWS BOTH VUGS AND SPHERICAL VESICLES. THE VUGS ARE CRYSTAL LINED. THE VESICLES ARE ALSO CRYSTAL LINED BUT have a smoother surface and may have some Glass in the lining. the fresh surface has a rough. hackly. fracture. the vugs are aligned along zones. the LINING OF IMPACT PITS IS CLEAR GLASS. CLEAR TO BROWN. HAS BOTRYOIDAL SURFACE. FELDSPAR AND PYROXENE LATHS RADIATE AWAY FROM OLIVINE CENTERS IN VARIOLITIC FORM. LATHS UP TO 3 MM LONG. OLIVINE ABOUT 1 MM DIAMETER. PYROXENE IS REDDISH BROUN. ABOUT 30 PERCENT OF ROCK. OLIVINE. YELLOW GREEN ( 10 PERCENT). ILMENITE. BLACK ADAMANTINE (15 PERCENT). FELDSPAR 45 PERCENT. HALVES PRCDUCE BRIGHTENING IN ALL MINERALS.
OLDER SURFACE OF ROCK BRIGHTENED AND SHATTERED BY IMPACT PITS. ROCK IS NOT FRAGILE. CRYSTALS APPEAR TO BE ALIGNED AROUND SPHERICAL VESICLES AND PARALLEL TO VUGS. NO OBVIOUS LAYERING OR LINEATION. ONE FRAGMENT INCLUSION OF BRECC\&A. IT WAS ANGULAR. CONTAINS A CLEAVAGE. IS OUITE FRIABLE. BUT IS a ROCK. VERY FINE GRAINED BUT PARTICULATE WELDED MATERIAL. MEDIUM BROWNISH GRAY. THE BOUNDARY BETWEEN BRECCIA AND ROCK IS VERY SHARP AND SMOOTH. IT IS POLYGONAL AND HAS SHARP CORNERS. THE MELT WAS ON THE SURFACE aND the breccia FELL INTO IT. SOME PYROXENE CRYSTALS ARE UP TO 5 mm LONG AND GIVE the texture a PORPHYRITIC TEXTURE. OLIVINE BASALT.

Fi.gure A-34. - Sample 12044.

Sample no. 12045 veight 63 grams dahlem
flat. tabular. one side is flat and the other is convex. the surface is SLIGhtly rounded but fine texture is hackly with some slight rounding. relief IS approximately \(1 / 2\) mm. SURFACE IS mottled dark gray. texture is granular average grain size is less than \(1 / 2\) mm. only a few fractures visible and are not thru going. some fractures have a discolored zone of dull gray and goes to light gray. no apparent stratification and no apparent major structure FEATURES.
SURFACE IS PItted with small glass lined pits ranging from less than o.5 up to 1.5 MM IN DIAMETER. GLASS LININGS OF PITS ARE VITREOUS. BLACK TO BRGWN. RANGE from even vitreous to fine grained even lusters. circular pits are commonly surrounded by scatter zone. transcending mineralogy. the outer contacts are ir Regular against shatter zone and is adophylitic intruding the matrix. windous in glass lining are rare. but do alloy a view of shattering in bottom of pits. internal reflection is visible in glass lining. the linings are LOCALLY SEVERELY fRACTURED. ON fLAt SURFACE RANGE IS FROM 7 TO 14 CMz felospar with lofcmz being average. the average pit size on convex side is approximately 1.0 ma. the pit lining occasionally includes grains of olivine. vugs RANGE FROM APPROXIMATELY 1.0 MM TO COELESCING GROUPS UP TO 5.0 MM. RANGE IN DEPTH FROM LESS THAN 1.0 MM UP TO 3.0 MM. WALLS INCLUDE ALL MATRIX MINERALS. most obvious being opaque mineral. which is euhedral. most of surface is COVERED WITH FINES.
1. the rock has 55 percent brohnish gray equant pyroxene less than 0.5 mm average grain size. prismatic with 2 wall level cleavages.
2. White. greenish white. tabular. plagioclase 20 percent maximum grain SIZE APPROXIMATELY . 8 MM LONG . 3 MM WIDE.
3. apple green. equant mineral 10 percent. occurs as 0.5 mm average SIZE. IN DISCRETE INDIVIDUAL AND MULTIGRANULAR SEGMENTS UP TO 1.0 MM IN DIAM.
4. opaoue. dark gray. metallic luster. tabular. wedge shaped habit.

COMmONLY EOUANT 7 TO 10 PERCENT.
5. Local areas of very fine grained granular material of all matrix minerals but very fine cless than 0.1 mm). local areas in these with extended trains of opaoue material transcending fine grained mass.
scattered in the matrix are whisps and individual of red brown material within feldospar and along grain boundaries between grains. occurrence of fine trains of opague material is fairly common in this sample. it is found in both fine grained material and in pyroxene grains. these are probably exsolution phenomena. the pyroxeneiopaouegolivine intergrowth is most obvious. called a basalt.

SAMPLE NO. 12045 WEIGHT 63 G DIMENSIONS \(5 \times 3.5 \times 2.0 \mathrm{CM}\) WONES neutral color. shape flattened ellipsoid. broken very fine grained. vuggy OLIVINE PHENOCRYSTS. Figure A-35.- Sample 12046.

SAMPLE NO. 12047 WEIGHT 193 GRAMS DIMENSIONS \(9 \times 2.5 \times 6\) CM HEIKEN tabular. subrounded rock. medium gray. holocrystalline. medium grained. feLDSpar are grouped in small radial bunches. a few vesicles up to 8 mm in diameter. some are coelescing. all are spherical. none ovoid. other than feldospar there is no obvious lineations. or oriented crystals. in a 1 cm circle there is an average of 1 glass lined impact pit. some pits do not have haloes the glass is blackish brown. has a bubbly surface.
ONE CM DIAmeter circle on bottom Gives 8 SURFACE pits about 0.8 mm across. CRACK WHICH IS HELD TOGETHER BY AN IMPACT PIT. MEDIUM GRAINED BASALT. medium gray. under scope consists of brownish mineral. white mineral and metallic lusterous mineral. hypiediomorphic granular two systems of fractures one parallel to plane of sample and second is conc. with respect to rounded edges on one end . the first is more persistent. one system of coelescing vugs on one side through which a fracture parallel to long dimensicin CUTS the fracture does not cut one of the glass lined pits on the surface. tho parallel fractures repeating at approximately 2 mm intervals. dust still adheres to all sides even though it has been bloun considerably. Glassy patches and glass lined circular pits are common ranging in size up to approximately 2.0 mm with depth . 1 mm. Splotches are botriodal. specular. vitreous to very fine grained granular specular. at least one shous concentric. ribbed texture inside pit. the pits are more abundant on one side than the other. the side with vug and fracture system has mere pits. the flatter side has fewer large pits but they are 3 mm in diaheter. the glass lining of pits on flat side is brounish but on rounded side is black. some evidence of eroding of area around pits hil ch leaves a raised lip CN pits. the oust covering is heavier on flat side. the glass linings are someyhat fractured becruse of newton rings of fractufie seen. on rounded side the range in pitsocmz is from 4 TO 12 and average is approximately 7 In pits greater than 0.5 mm. on flat side the range of pits greater than 0.5 mm is 2 to 5 with 3 to 4 being average. the haloes extend irrespective of mineralogy up to one crater diameter. the minerals are felospar and milky pyroxene. some are chalky and fine grained enough to have lost luster. two other types of defressions. first is Spherical with euhedral crystals lining walls. second is a vug. lined with euhedral crystals characteristic of matrix. may be tendency of feldipar to concentrate in vugs. the flat large side may have been down. but tumbling is COMPLEX.
FOUR PHASES.
1. tan. cream. phase. pyroxene 40 percent of rock.
2. WHITE TO CLEAR PLAGIOCLASE 30 PERCENT
3. black metallic opaoue. probably ilmenite 20 percent
4. apple green probably olivine approxiamtely 5 percent
5. 5 PERCENT UNDECLARED
1. EQUANt to SLightly elongate. occurs principally (interstitially with) as Space filling between plagioclase grains. average . 3 to . 4 mm
2. tabular. ranges up to 1.5 mm long and 0.5 mm across. twinning is lamellae and perpendicular to lamellae. commonly in semi radial habit in clumps with no intergrown pyroxene and opaques. some carlsbad twinning. some CLUMPS ARE APPROXIMATELY 1.5 MM ACROSS.
3. scattered at random. planar habit. some pie shaped and commonly INTERGROWN WITH PYROXENE.
NO ALTERATION IS APPARENT IN ANY MINERALS. glass pit lining. in one case includes a fused lath of feldospar. the glass is dark even toned except for diameter oriented clear swath. called a microgabbro.

Fi.gure A-36. - Sample 12047.

SAMPLE NO. 12051 WEIGHT 1660 DIMENSIONS \(16 \times 11.5 \times 7\) CM HEIKEN LOAF SHAPED ROCK. BOTTOM IS A PLANAR FRACTLRE SURFACE. THE BOTTOM IS A DARK BROWNISH GRAY. A SERIES OF SPALLATION TYPE FRACTURES PARALLEL TO THE BOTTOM OF THE ROCK. THE EDGES OF FRACTURE ARE VERY ANGULAR. UPPER PART IS VERY ROUNDED. LIGHT BROWNISH GRAY. THERE IS A DISTINCT COLOR DIFFERENCE BETWEEN IOP AND BOTTOM. TEXTURE IS HOLOCRYSTALLINE. MEDIUM GRAINED. MOST CRYSTALS ARE randomly oriented. some have a variolitic texture. one deep fracture visible and Cuts thru the bhole rock. there are surface areas which do not NECESSARILY HAVE VESICLES BUT HAVE A DICTYTAXITIC TEXTURE. SOME VESICLES PRESENT UP TO 4 mM DIAMETER. THERE ARE SURFACE GLASS LINED PITS FROM 0. 1 TO 2 MM IN DIAMETER. THE GLASS LINING IS APPROXIMATELY. 2 MM THICK WITH A BUBBLY SURFACE. THE GLASS HAS MULTIPLE COLORS FROM COLORLESS TO BLACK CAUSED BY FUSION OF CRYSTALS IN PLACE. THE WHITE CORONA OF CRUSHED MINERALS IS APPROXIMATELY \(1 / 2\) CRATER WIDTH WIDE. RANDOM 1 CM WIDE AREAS GIVE 6 AND 2 AND 3 AND 3. SOME VERY THIN SPLASHES OF BLACK GLASS ON A SLIGHTLY WEATHERED SURFACE. THE SPLASHES ARE APPROXIMATELY 1 TO 2 MM ACROSS WITH IRREGULAR bOUNDARIES. THE FLAT bASE HAS NO SURFACE PITS OR GLASS SPLOTCHES AND has a much oarker color because there are no minerals fractured or shattered. there IS GRAY DUST ADHERING TIGHTLY TO THIS SURFACE.
FELDSPAR APPROXIMATELY 45 PERCENT. AVERAGE LENGTH OF LATHS IS APPROXIMATELY 1 MM. COLORLESS TO MILKY WHITE.
PYROXENE APPROXIMATELY 30 PERCENT. REDDISH BROWN PYROXENE SUBHEDRAL CRYSTALS . 5 TO 1 MM LONG.
OLIVINE OR PYROXENE APPROXIMATELY 15 PERCENT. VERY LIGHT GREENISH YELLOW APPROXIMATELY . 5 MM DIAMETER. EQUANT CRYSTALS.
ILMENITE APPROXIMATELY 10 PERCENT. VERY THIN BLADED CRYSTALS UP TO 3 MM LONG. and sime small more equant crystals.
NEAR VESICLES AND VUGS ARE EUHEDRAL ERySTALS OF ALL TYPES MENTIONED ABOVE. BUT SIZES ARE NOT ANY LARGER.

Figure A-39. - Sample 12052.

SAMPLE NO. 12053 WEIGHT 879 G DIMENSIONS 12 CM X 8.5 CM X 5 CM GREENVOOD OLIVIne basalt. rock has a flat bottom with angular edges and a subrounded peaked top. the top surfaces are pitted with a smooth peppered rounded surface medium grey outside except for a lustrous black glass which lines some pits. these are also infrequent 2 to 3 mm vesicles. which are lined with crystals . the glass lined pits have a bright thalo of fractured rock around them. the bOTTOM SURFACE HAS A SMALL \(1 \times 1\) CM PATCH OR BLACK CRYSTAL. A FRESH SURFACE has same color as weathered (men!ju gpey and there is a subplanar fracture set parallel to the base.
There is also a Set of (intersecting) fractures which at 40 degrees and the base plane bisects the small angle between the fractures. the rock is fine grained. with needles of feldospar up to 3 mm long. trachytic texture. the vesicles are lined with fine minerals. rather than glass. the mafic minerals appear to be yellow green olivine ( 10 PERCENT). DARK GREY matrix ( approximately 25 percent). there is an opaoje mineral ilmenite or magnetite. 2 or 3 percent. feldispar 60 percent. the vesicles are lined with coarser crystals of the matrix. the vesicle crystals are pyroxene and olivine. the texture tends to dictytaxitic and the rock is holocrystalline granular. the black cofting on bottom is botryoidal glass. there is no apparent overall preferred crystal orientation. locally the feldospar crystals appear to have a rosette habit. the ROCK IS NOT FRIABLE OR FRAGILE. THE ROCK IS ABOUT 5 PERCENT VOIDS CCRYSTALLINE lined vesicles). there are numerous impact pits on the top of the rock. no impact pits were seen on the bottom. no alteration except for impact fracturing WAS SEEN.
one side is angular to subangular with thin exfoliation type fractures on one side. the other side is well rounded with considerable dust adhering tightly to rounded side. fine grained holocrystalline. moist crystals approximately 0.2 to 0.3 mm long. equigranular most crystals are lath shaped sometimes appearing in bunches growing radially out from a central point.

FELDSPAR 60 PERCENT
PYROXENE 20 PERCENT CInnamon brown elongate lath shaped
ILMENITE 15 PERCENT BLADED
OLIVINE 5 PERCENT VERY LIGHT GREEN
the surface is covered with
Shallov pits from \(1 / 20\) TO 1 MM. NUMBER OF PITS IN A CIRCLE 1 CM IN DIAMETER. 32 PITS IN FIRST COUNT. 15 PITS IN SECOND COUNT.
on top is a very thin glass spatter approximate 6 mm in diameter with irregular edges. very oark brown. in a number of instances. the glass lined pits are raised slightly above the rock surface. it appears that the rock has been differentially eroded. with glass linings as resistant highs. four vesicles on upper surface all less than \(1 / 2\) mm in diameter. angular (bottom) side irregularly spaced vesicles approximately 1 ma in diameter averaging approximately 1 PER CM CIRCLE LINING walls of vesicles are abundant OLIVINE CRYSTALS APPROXIMATELY 2 MM ON LONG AXIS . NO IMPACT PITS ON BOTTOM. on bottom is a patch of thin glass spatter \(0.5 \times 0.6 \mathrm{Cm}\). the surface is highly ir
the following experiment was conducted on this sample
RCL ANALYSIS

Figure A-40. - Sample 12053.

SAMPLE NO. 12054 WEIGHT 687 GRAMS DIMENSIONS \(9 \times 7 \times 7\) CM GREENHOOD HIGHLY ANGULAR NO ROUNDING. PYRAMIDAL SHAPED BASE IS COVERED WITH BLACK GLASS THIN COAT OF VESICULAR GLASS APPROXIMATELY \(1 / 4\) MM THICK. THE GLASS COVERS UP approximately \(1 / 2\) Way up the pyramid. the rock is light gray. medium to coarse CRYSTALLINE FELDSPAR LATHS ARE 2 TO 3 MM IN LENGTH. LIGHT GREENISH BROWN MATRIX PYROXENE. COARSE 7 MM PHENOCRYST OF PYROXENE APPEARS EUHEDRAL. THE PYRAMID TOP OF ROCK APPEARS TO BE A SHATTERCONE. THERE ARE CONVERGING SLICKENSIDED SURFACES WITH GROUND UP AND SMEARED OUT MINERALS. THE BASE OF THE PYRAMID has one large and several small open fractures. the fractures are welded TOGETHER BY GLASS. THE ROCK APPEARS TO BE EXPANDED WITH BREADCRUST FASHION and IS HELD TOGETHER BY THE GLASS. at THE TOP OF THE PYRAMID IS a FRACTURE WITH A VEIN FILLED WITH REDDISH YELLOW GLASS. THE ROCK IS VERY FRIABLE AND FRAGILE AND MUCH FRACTURED UP. IN ADDITION TO GLASS COAiIiNG ADJACENT TO IT aND EXTENDING BEYOND THERE IS A BROWNISH BLACK DULL COATING ON ROCK THAT GOES INTO FRACTURES. IT IS DARKER THAN MEDIUM GRAY DUST AND APPEARS RELATED TO EVENT THAT CAUSED GLASS. IT IS THIN LESS THAN O.I MM AND IS EASILY SCRATCHED OFF WITH A NEEDLE. IT MAY BE EITHER BAKED DUST BELOW GLASS. WHICH WAS CHIPPED OFF OR A CHEMICAL SUBLIMATE ON THE ROCK.
at the intersect ion of open fractures the rock is granulated and some fractures HAVE BLACK GLASS FILLINGS. THE PYROXENE IS MICROFRACTURED ALSO AND THE FELDSPAR IS WITHOUT CLEAVAGE AND IS WHITE - THERE SEEMS TO BE A NUMBER OF IMPACT PITS THROUGH THE GLASS AND INTO THE ROCK. THE IMPACT PITS ARE GLASS LINED AND APPEAR TO HAVE BEEN SPALLED OUT. THE GLASS HAS A YELLOW BROWN INTERNAL REFLECTION WHERE ITS THIN. IT HAS A NUMBER OF BROWN VESICLES SOME GLASS IN PITS IS LIGHT COLORED. LIGHT BROWN YO CLEAR. THERE APPEARS TO BE A NUMBER OF SMALL SPHERULES APPROXIMATELY 2 MM IN DIAMETER TO 5 MM BONDED TO THE SURFACE. THERE IS NO EVIDEPSE OF The GLASS altering the rock below it. the liouid must have BEEN OF VERY LOW VISCOSITY TO SPREAD SO THIN AND TO GO INTO THE FRACTURE. WHERE
 GLASS AND SURROUNDED BY a HALO OUT TO 1 CRATER DIAMETER OF SHATTERED GLASS OF a LIGHT YELLOW BROWN COI.OR. THERE ARE A GREAT NUMBER OF THESE SMALL PITS IN THE GLASS. THE PITS GREATER THAN 1 MM GO INTO THE ROCK. LESS THAN 1 MM DO NOT. THE LARGER ONES BLAST AMAY THE GLASS AND HAVE A DARKER GLASS LINING OF GLASS. the rock itself has plagiociase laths. it has a trachytic texture. holoCRYSTALLINE. MAY BE a SUBTLE ORIENTATION OF plagioclase crystals near the base. fragments of this rock type are belded to the outside of the glass. there may be an Impact pit on one of the sides that is in general glass covered. the pit IS GLASS LINED APPROXIMATELY 3 MM ACROSS BUT THE AREA AROUND IT IS FREE OF GLASS THE ROCK IS THOROUGHLY FRACTURED WITH SUBPOLIGONAL FRACTURE SETS AND APPEARS TO BE EXPANDED ON A MICROSCALE. FRACTUR'S EXTEND THROUGH BLADES OF ILMENITE AND OTHER CRYSTALS. FELDSPAR IS APPROXIMATELY 50 PERCENT OF THE ROCK. THERE ARE DARK PYROXENE PHENOCRYSTS THROUGHOUT THE ROCK. NO VUGS IDENTIFIABLE. BONDED TO THE OUTSIDE OF THE GLASS THERE ARE CRYSTALS OF FELDSPAR AND PYROXENE YHICH are semitranslucent and appears in the rock with its glass coating. the rock WITH ITS GLASS COATING appears to have fallen on soil while the glass was still not bonding the soil to the rock. several of the fractures radiate out frgm the CENTER IN CARTWHEEL FASHION. THE FELDSPAR IS HIGHLY ALTERED BY SHOCK. THERE IS A REDDISH BROWN ACCESSORY MINERAL THAT IS PRISMATIC IN HABIT APPROXIMATELY 1/10 MILLIMETERS IN LENGTH.

THE ELONGATE FELDSPAR LATHS. PYROXENE CRYSTALS. AND BLADES OF ILMENITE ARE ALL SUBPARALLEL IN RADIALLY ORIENTED CLUMPS. THE CLUMPS ARE APPROXIMATELY 5 TO 8 MM IN DIAAMETER AT JUNCTIONS BETWEEN CLUMPS ARE SMALL MORE EQUANT CRYSTALS OF ILMENITE. VUGS WITHIN fractures are filled with well formed crystals of all fypes described. SHAPE. ELLIPSOIDAL. ONE END BROKEN OFF.
COLOR. NEUTRAL N7
TEXTURE. VUGGY. MEDIUM GRAINED. SUBJPHITIC.
FABRIC. NO OBSERVED LINEATIONS. RANDOM VUGS. 2 CM DOHN TO 2 MM . NO VESICLES. FRACTURES. THROUGH GOiNG FRACTURES APPROXIMATELY PARALLEL TO SURFACE SHAPE OF ROCK IS CONTROLLED BY FRACTURES.
SURFACE FEATURES. GLASS LINED PITS COMMON ON ALL SIDES 1 TO 4 MM IN DIAMETER. SOME SHATTERED TEXTURE ON SURFACE. ROUNDING INDENTATIONS PRESENT. LARGE PITS AND ROUNDING COMMON ON ROUNDED END OF ELIPSE. BOTTOM HAS A FRESH BROKEN SURFACE. MINERALOGY. MODE.

PLAGIOCLASE 45 PERCENT
PYROXENE 50 PERCENT
OLIVINE 5 PERCENT
opaQues. thin blades approximately 1 percent
PLAGIOCLASE UP TO 1 CM LONG. 04 MM WIDE. SOME IS 1 MM X 0.2 MM. SOME TIMES OCCURS AS SHEATHS. CLEAR TO WHITE.
PYROXENE EQUANT \(1 \times 1\) MM GRAINS BROWN.
OLIVENE. 0.4 EUHEDRAL EQUANT GRAINS.
OPAQUES. BLADED BLACK. \(0.1 \times 0.01\) MM.
VUGS. DOMINANT MINERAL IN VUGS IS PYROXENE. APPEARS TO BE PLAGIOCLASE AND OLIVINE IN VUGS TOO. PYROXENES ARE APPROXIMATELY I CM LONG APPROXIMATELY 0.8 MM WIDE. RANDOM ORIENTATION. NO CHANGE IN GROUND MASS NEXT TO VUG. PYROXENE APPEARS DARKER BROWN THAN PYROXENE WITH GROUND MASS. SHOCK ALTERATION OF SURFACE MINERALS. CALL it an olivine basalt.
SIDE 2 (BOTTOM) SUBROUNDED APPEARS TO HAVE AS MANY GLASS LINED PITS AS OTHER SIDE. TEXTURE IS SAME AS SIDE 1 WITH EXCEPTION THERE IS APPROXIMATELY 5 percent by volume of ovoid vesicles. the vesicles are lined with all VARIETIES LINING THE walls parallel to walls with exception of a large COELESCED VESICLE WITH TOTAL LENGTH OF APPROXIMATELY 16 MM. THE CAVITIES are PARTIALLY FILLED WITH INTERTWINED PYROXENE CRYSTALS UP TO 5 MM LONG WITH SLIGHT GREENISH TINGE. THE SIDES OF THE ROCK HAVE NUMEROUS GLASS LINED PITS ALSO.

SAMPLE NOS. 12057.14 AND 12057.15 SECTIONS FRONDEL MICROGABBPCS THAT HAVE BEEN SEVERELY SHOCKED (SEE PHOTOGRAPHS). SHOWS granulation. bending and dislocation of tiin lamellae in plagioclase. etc. CRISTOBALITE PRESENT IN BOTH ROCKS. IN PART EUHEDRAL AND IN PART AS SKELETAL CRYSTALS. THE ACCESSORY ILMENITE iS SMALLER AND MORE EOUANT IN HABIT THAN USUAL.

SAMPLE NO. 12057.15 STANDARD THIN SECTION WILCOX COARSE GRAINED SUBDIABASIC TEXTURE. \(\operatorname{VITH}\) MUCH FRACTURING OF CRYSTALS (SHOCK). BUT VERY LITTLE DIFFERENTIAL DISPLACEMENT. CRYSTALS AND PLATES UP TO \(21 / 2\) MM LONG. SOME IN SUBRADIAL CLUSTERS.
APPROXIMATE MODE.
CLINOPYROXENE 45 PERCENT
PLAGIOCLASE 40 PERCENT
OPAQUE OXIDE 10 PERCENT
CRISTOBALITE OR TRIDYMITE 4 PERCENT
CLINOPYROXENE OCCURS IN LONG CRYSTALS. INTENSELY FRACTURED. SOME WITH STRONGLY DEVELOPED LAMELLAE TYINNING (FROM STRESS). COLOR ZGNED FROM VERY PALE BROWN at Centers to brounish red at edges. optic angle positive. variable o to 35 DEGREES. EXTERIOR ANGLE LARGE, ZAC NEAR 45 DEGREES OR GREATER. PLAGIOCLASE APPEARS TO BE CALCIC. PERHAPS AN70 TO AN901 EST. FROM RELIEF AND HI EXTERIOR ANGLES. CRYSTALS ARE VERY LONG, VITH BROAD LAMELLAE THINNING MUCH SHATTERED BUT NOT SEPARATED. OPAOUE GRAINS OCCUR IN LONG CROSS SECTIONS (PLATES) VERY DARK GRAY IN REFLECTED LIGHT (FLASHLIGHT ON UNPOLISHED SURFACE). (A FEW YELLOW REFLECTING SMALL masSes are scattered through the rockj.
CRISTOBALITE OR TRIDYMITE. MASSES OF STRONG NEGATIVE RELIEF AND VERY LOW VARIABLE BIREFRINGENCE ARE NOT UNCOMMON. THEY RANGE UP TO SEVERAL TENTHS OF a mM IN length and have geometrically straight sides in many cases. they have a very pale brown color. Surface texture is wrinkled. reticulated. reminisCENT OF CRISTOBALITE. SECTION ACROSS ONE MASS OF THIS MATERIAL ABOUT \(0.2 \times 0.3\) MM SHOUS INCLUSIONS OF PYROXENE AND OPAOUES.

SAMPLE NO. 12057.5
HARMON
STEREO MICROSCOPE EXAMINATIONS OF AN APPROXIMATE 1 CM3 CHIP. A HOLOCRYSTALLINE HIGHLY SHOCKED ROCK. MICROGABBRO.
MINERALOGY.
phases readily identifiable are described as follows.
1. GROUNDMASS MATERIAL. VERY FINE GRAINED. WHITE COLOR. WITH A SUGARY TEXTURE. SOME GRAINS LARGE ENOUGH TO BE SEEN UNDER \(4 X\) MAGNIFICATION aRE lath shaped. the groundmass material. on the whole. appears to have a poor to falr cleavage. a plagioclase feldspar. highly shocked causing the GRANULAR TEXTURE. A PLAGIOCLASE FELDSPAR 30 PERCENT.
2. MAJOR MINERAL PHASE PRESENT. GRAIN SIZE RANGING UP TO 1 MM. A BROEN GREEN COLOR. LARGER CRYSTALS SHOW GOOD CLEAVAGE. MOST GRAINS ARE HIGHLY FRACTURED. CLINGPYROXENE APPROXIMATELY 50 PERCENT.
3. SECOND MAJOR MINERAL PRESENT. VERY PLATY HABIT. WITH A BLACK COLOR. THESE GRAINS CROSSCUT ALL OTHERS AND THE PLATES RANGE UP TO 0.3 CM IN LENGTH. ILMENITE APPROXIMATELY 15 PERCENT.
4. ACCESSORY PHASE. COLORLESS. CLEAR. OCCURRING IN EQUANT GRAINS USUALLY VERY ANGULAR WITH A SEMICONCHGIDAL FRACTURE. ANORTHITE FELDSPAR APPROXIMATELY 5 PERCENT.

Figure A-47. - Sample 12057-5 (NASA-S-69-61395).

Sample 12057-6

SAMPLE NO 12057.17 THIN SECTION FRONDEL
COARSE GRAINED MICROGABBRO. VITH CLINOPYROXENE. ANORTHITE. ILMENITE. ABUNDANT CRISTOBALITE AND VERY LITTLE OR NO OLIVINE. A FEW GRAINS OF AN UNIDENTIFIED pale yellow mineral were observed. not pleochroic.

SAMPLE NOS. 12057.18 AND 12057.17 THIN SECTION
FRONDEL OBSERVATIONS ON CRISTOBALITE IN SAMPLES.
CRISTOBALITE IS ABUNDANT IN THESE MICROGABBROS. IT IS GENERALLY EUHDDRAL TO SUB hedral and ranges in grain size up to about 0.5 mm. the crystals were ORIGINALLY HIGH CRISTOBALITE THAT HAVE INVERTED TO A MICROGRANULAR aGGREGATE OF LOW CRISTOBALITE. THERE IS A CONSIDERABLE DEGREE OF PREFERRED ORIENTATION IN THE GRAINS OF THE INVERSION PSEUDOMORPHS. AS SHOWN BY THE NEARLY UNIFORM EXTINCTION BET甘EEN CROSSED NICOLS AND BY THE PARALLEL ALIGNMENT OF INDIVIDUAL SETS OF INVERSION TWINS. THE HIGH CRISTOBALITE CRYSTALS APPEAR TO BE OCTAheDrons flattened on a (1111) face. SOME CRYSTALS were hexagoreal in outline WITH LATERAL EDGES ALTERNATELY SLOPING UP AND DOWN.J LATERAL SECTIONS THROUGH these tabular crystals are elongateg generally with six edges (or facesj. TRIDYMITE 甘AS NOT IDENTIFIED WITH CERTAINTY IN THESE ROCKS ALTHOUGH IT OCCURS TOGETHER WITH CRISTOBALITE IN APOLLO 11 ROCKS. CRISTOBALITE ALSO WAS OBSERVED TO OCCUR IN SKELETAL CRYSTALS RESEMBLING FOUR LEAFED CLOVERS (SEE PhotographS OF THESE AND OF OTHER CRISTOBALITE CRYSTALSJ.

Figure A-48، - Sample 12057-6 (NASA-S-69-61406).

Sample 12057-7

SAMPLE NO. 12057.13 THREE CHIPS 12057.7 1.9 GRAMS HARMON
BINOCULAR MICROSCOPE EXAMINATION AND IMMERSION OIL GRAIN MOUNTS. THE CHIP IS HOLOCRYSTALLINE. WITH A GRANULAR TEXTURE. GRAINS OF ALL HINERAL PHASES PRESENT are generally equant with grain size ranging up to 0.2 mm. the chips all have a VERY FRESH LOOKING APPEARANCE. SMALL (0.1 TO 0.5 MMJ IRREGULAR CAVITIES (VUGS) are present in all of the chips but no increase in grain size of the minerals surrounding these cavities Is observed. one of these chips sent for AA CHEMICAL ANALYSIS. MINERALOGY.
the sample is basically composed of four mineral fhases. three primary phases AND ONE ACCESSORY PHASE.
1. A MILKY WHITE TO COLORLESS MINERAL. GENERALLY EQUANT TO LATH SHAPED. OCCURRING IN AGGREGATES. TWO POOR FAIR CLEAVAGES. THE M!LKY WHITE GRAINS ARE always smaller and more fractured than rhe clear. colorless grains. index of REFRACTION APPROXIMATELY 1.57. GRAIN SIZE UP TO 0.2 MM. EXCELLENT POLYSYNTHETIC TWINNING FELDSPAR (ANORTHITE) APPROXIMATELY 35 PERCENT.
A. A COLORLESS MINERAL. OCCURS AS PLATELETS IN PARALLELOGRAM AND
polygonal shapes. the base fleavage is excellent. grain size is generally LARGER THAN THAT OF THE FELDSPAP DESCRIBED ABOVE. RANGING UP TO 2.0 MM. INDEX OF REFRACTION LESS THAN 1.48. ISOTOPIC WITH ABUNDANT INCLUSIONS. (MAY BE A SHOCKED FELDSPAR. MORE ACIDIC THAN THE PURE ANORTHITEJ APPROXIMATELY 5 PERCENT. PRIMARILY OCCURRING IN THE VUGS IN THE ROCK NOT SEEN AT ALL IN THE GROUNDMASS. this may be a contaminant.
2. A HONEY YELLOW TO BROWN MINERAL. GENERALLY EOUANT GRAINS. GRAIN SIZE RANGES UP TO O.5 MM. SOME GRAINS SHOW A POOR/FAIR CLEAVAGE AND OTHERS HINTS OF A PRISMATIC HABIT. INDEX OF REFRACTION GREATER THAN OR EQUAL TO 1.71. MODERATE BIREFRINGENCE. EXTINCTION ANGLE APPROXIMATELY 35 PERCENT. CCLINOPYROXENE/PIGEONITEJ APPROXIMATELY 40 PERCENT.
3. A bLACK OPAQUE MINERAL. GRAINS ARE IRREGULARLY SHAPED. GRAIN SIZE RANGES UP TO 1.0 MM WITH MOST GRAINS ABOUT O.5 MM. MUCH SMALLER GRA INS OCCUR as inclusions in all the other mineral phases present. some grains have a PLATY HABIT. (ILMENITEJ APP\&ROXIMATELY 20 PERCENT.
4. A GREEN MINERAL. GRAINS ARE EQUANT WITH GRAIN SIZE AVERAGING ABOUT 0.5 MM. ONE GRAIN OBSERVED SHOWED ELONGATION INTO A PRISMATIC HABIT WITH THE LONG AXIS \(2 \times\) the OTHER aXIS. mOSt GRAINS have inclusions of the black opaoue MINERAL. FRACTURING IS SEMI CONCHOIDAL. INDEX OF REFRACTION GREATER THAN 1.71 (OLIVINE) APPROXIMATELY 5 PERCENT.

SECTION 120057.18 CHIP FROM ROCK 1 TO 6 IN DOCUMENTED BOX. M. R. GREENHOOD DECEMBER E. 1969
a medium fine grained helocrystalline rock caverage grain size approximately 1 MMJ WITH TRACHYTIC TEXTURE. COMPOSED OF

3. ILMENITE 7 PERCENT
4. LIGHT YELLOW GREEN ORTHOPYROXENE APPROXIMATELY 3 PERCENT
5. OLIVINE APPROXIIMATELY 2 PERCENT
6. CRISTOBALITE APPROXIMATELY 2 PERCENT
7. ACCESSORIES. RUTILE AND REACT. ZONES APPROXIMATELY 1 PERCENT
the clinopyroxene and the plagioclase are compositionally zoned.
OLIVINE IS COMMONLY FOUND AS CORES OF CLINOPYROXENE CRYSTALS WITHOUT A REAC. OF RIM. WHERE ORTHOPYROXENE IS HANDED IN PART BY CLINOPYROXENE AND IN PART BY plagioclase a complicated reaction zone is formed between both the pyroxenes and between orthpyroxene and plagioclase. the intergrowth includes a clear LOW BIREFRINGENT HIGH RELIEF GLOBULAR TO SAUSAGE SHAPED MINERAL WHICH GROWS IN the plagioclase and in the pyroxene.
THE HIGH RELIEF MINERAL IS ENCLOSED IN A LOW RELIEF AND BIREFRINGENT ZONE IN THE PLAGIOCLASE. A FIBROUS. FINE GRAINED. INTERGROWTH OF A HIGH RELIEF AND BIREFRINGENT MINERAL AND OPAQUES REPLACE ORTHOPYROXENE. CRISTOBALITE TO HAVE CRYSTALLINE FROM THE RELIEF LIOUID INTO WHICH THE LAST PLAGIOCLASE WAS GROXING alternatively it could be on solid state replacement growth. ONE LATH OF plagioclase appears to nucleate or and grow parallel to both sides OF a CLINOPYROXENE BLADE WITH INCREASING SODIUM CONTENT THROUGH TIME. LATHS OF CLINOPYROXENE TEND TO GROW FROM COMMON NUCLEATION CENTERS TO DEFINE SECTIONS of CRystallization. these nucleation points may have been crystals of olivine and ORTHOPYROXENE IN THE MELT. SIMULTANEOUS GROWTH OF PLAGIOCLASE ON THE CLINOPYROXENE PRODUCED LONG BLADES WHICH TEND TO DOMINATE LOCAL TEXTURE CUP TO 1 CM ACROSSJ. DIFFERENT NUCLEATION CENTERS HAVE DIFFERENT ORIENTATI ON PATTERNS. perhaps due to out effect. the boundary zone between the nucleaticn sectors has mORE COMPLICATED INTERGROYTHS OF CLINOPYROXENE AND PLAGIOCLASE AND SOME SHEARING AND RECRYSTALLIZATION ALSO PERHAPS A HIGHER CCNTENT OF CRISTOBALITE. CRISTOBALITE CONTAINS TINY SAUSAGE SHAPED RED BROWN HIGH RELIEF inclusion that may be rutile.

SAMPLE NO. 12057.18 HARMON
THIN SECTION EXAMINATION OF A CHIP OF 12057.17 UNDER THE PETROGRAPHIC MICROSCOPE.
the sample IS holocrystalline with a medium to mecium coarse grain size with FIVE MAJOR MINERAL PHASES PRESENT. SOME SMALL CAVITIES AND FRACTURES PRESENT.
1. PLAGIOCLASE FELDSPAR. GENERAL OCCURRENCE IS LATH SHAPED GRAINS WITH VERY IRREGULAR BOUNDARIES • OFTEN GRAINS ARE VERY MUCH ELONGATED IN ONE DIRECTION. MaNy OF the GRaIN BOUNDARIES OF the feldSpars are cut by all of the OTHER PHASES PRESENT. BUT IN SO\&A CASES FELDSPAR GRAINS ENCLOSE PYROXENE GRAINS. SOME OF MORE ELONGATE GRAINS RANGE UP TO OVER 1 MM IN LENGTH \(W\) ITH THE AVERAGE GRAIN SIZE BEING ABOUT O.S MM. MOST GRAINS SHOW TYPICAL FELDSPAR TKINNING AND DO NOT APPEAR TOO SHOCKED. NO PREFERRED ORIENTATION OF THE FELDSPAR GRAINS WAS NOTED.
2. CLINOPYROXENE . GENERAL OCCURRENCE IS IN EQUANT TO PRISMATIC GRAINS. MANY OF THE GRAINS SHOW MORE HIGHLY DEVELOPED CRYSTAL FORMS THAN THE FELDSPAR INDICATING AN EARLIER CRYSTALLIZATION. SOME GRAINS REACHING 1 MM IN SIZE ARE PRESENT. BUT THE AVERAGE GRAIN SIZE IS ABOUT 0.3 MM.
3. OPAOUE OXIDE (ILMENITEJ. GENERAL OCCURRENCE IS IN PLATY TO IRP.EGULARLY SHAPED OPAQUE GRAINS. THE LARGER BETTER DEVELOPED GRAINS ARE 0. 2 TO 0.3 MM LONG AND CUT ACROSS ALL OTHER PHASES PRESENT.
4. OLIVINE. A VERY FEW EQUANT. HIGHLY BIREFRINGENT GRAINS WERE OBSERVED. SEMI CONCHOIDAL FRACTURING. WITH GRAIN SIZE AVERAGING ABUUT 0.2 MM.
5. CRISTOBALITE. GENERALLY OCCURS AS BOTH INTERSTITIAL MATERIAL AND AS INDIVIDUAL GRAINS. LOWLY BIREFRINGENT. CHARACTERISTIC TWINNING AND GENERAL MOTTLED APPEARANCE. SOME LARGER GRAINS RANGE UP TO 0.3 MM.
TWO POINT COUNTS OF 500 POINTS WAS CONDUCTED WITH THE FOLLOWING RESULTS. NUMBER POINTS

UNKNOWN GREEN MINERAL 3 PERCENT
CRISTOBALITE 2 PERCENT
UNKNOWN GREEN MINERAL AS SCATTERED STUBBY CRYSTALS HAS PALE BOTTLE GREEN TO pale yellow green pleochroism in thin section. possibly 2 Cleavages at about 90 DEGREES. PARALLEL EXTINCTION. STRONG POSITIVE RELIEF, STRONG BIREFRINGENCE (NEAR 0.04) AND OPTIC ANGLE 2V NEGATIVE. SMALL (LESS THAN 30 DEGREES). IT SHOWS REACTION IN CONTACT WITH CLINOPYROXENE AND PLAGIOCLASE. IN REFLECTED LIGHT (FLASHLIGHT) THESE CRYSTALS ARE PALE POWDERY WHITE. AS IF DECOMPOSING. ELINOPYROXENE IS MOSTLY IN LONG CRYSTALS SLIGHT BROWN REDDISH COLOR. PLEOCHROISM WEAK OR ABSENT. SOME FAINT ZONING OF COLOR. SOME BUNDLES AND ROSETTES OF THIN CRYSTALS IN PLAGIOCLASE. OF SEVERAL \(2 V\) ESTIMATES NONE WERE LOWER Than 40 DEGREES. SLIGHTLY HIGHER BIREFRINGENCE ON RIMS OF SOME CRYSTALS.
plagioclase elongate. not strongly euhedral. only milo progressive zoning CALCIC COMPOSITION (BETVEEN ANGO TO AN 9O).
OLIVINE NEARLY COLORLESS. PRESENT AS CORES AND RELICS. NON EUHEDRAL. VITH OVERGROWTHS OF CLINOPYROXENE.
opaque grains many elongate plates. dark gray color in reflected light gflash
LIGHTJ. THERE ARE A FEW SCAYTERED BRIGHTLY REFLECTING GRAINS. CRISTOBALITE NOT EXAMINED IN DETAIL.

SAMPLE 12057.21
W. R. GREENHOOD

DECEMBER 6. 1969 OLIVINE GABBRO CHIEF DESCRIPTION
a holocrystalline eouigranular rock composed of
OLIVINE 45 PERCENT
CLINOPYROXENE 30 PERCENT
PLAGIOCLASE 20 PERCENT
OPAQUES 5 PERCENT
OLIVINE IS EUHEDRAL. SOME CRYSTALS HAVE CORES OF PYROXENE.
PYROXENE AND OLIVINE FORM aGGREGATE CLUSTERS WITH THE INTERVENING area filled WITH PLAGIOCLASE.
plagioclase is about an 64.
the overall texture appears envealed. no obvious zoning was seen in plagioclase OR PYROXENE. THE TEXTURE IS SIMILAR TO COMULATE TEXTURES IN THE STILL甘ATER. PYROXENE SHOWING TWINNING AND OR BINDING. OLIVINE CONTAINS NEGATIVE CRYSTALS. SOME OF WHICH ARE FILLED WITH FINE CRYSTALLINE INTERGROWTHS. SOME APPEAR EMPTY. THIS ROCK MAY BE THAT FRQM WHICH THE ANORTHOSITE WAS EXTRUDED.

SAMPLE 12057.21 HARMON
a 100 point count of the section was made with the following results.
PLAGIOCLASE 21 POINTS 21 PERCENT
CLINOPYROXENE 59 POINTS 59 PERCENT

SAMPLE NO. 12057.12 SMITH
ONE LARGER ( \(5.0 \times 4.4 \times 3.2 \mathrm{MM}\) ) AND THREE SMALLER (LESS THAN 2.5 MM) CHIPS. DARK GRAY BLACK VESICULAR ROCK PORPHYRITIC WITH SPHERICAL VESICLES RANGING FROM . 63 MM DOWN TO LESS THAN . 025 MM. THE LARGEST CHIP HAS ONE ROUNDED OUTER SURFACE WITH A PATCH OF CHALKY WHITE FELDSPAR THAT MAY REPRESENT AN EXPOSED OUTER SURFACE IN THE LUNAR ENVIRONMENT. THE CHALKY WHITE PATCH APPROXIMATELY 1.0 X 1.5 MM CONTAINS TINY AREAS OF MORE CLEAR PALE YELLOWISH CRYSTALLINE MINERAL.
ONE OF THE SMALLER CHIPS SHOWS A TINY GLASS LINED PIT.
ALL CHIPS CONTAIN PLAGIOCLASE AS PHENOCRYSTS OR XENOCRYSTS UP TO . 6 MM LONG. ONE PALE YELLOW OLIVINE PHENOCRYST APPROXIMATELY. 4 MM WAS REMOVED AND CHECKED OPTICALLY (SEE BELOW).
PETROGRAFHIC EXAHINATION OF GRAINS SHOWS THE PLAGIOCLASE (N GREATER THAN 1. SS)
TO BE XENOCRYSTIC IN A GROUNDMASS OF DARK BROWN GLASS (N GREATER THAN 1. S5).
FELDSPAR LATHS AND MINOR OLIVINE AND PYROXENE. PLAGIOCLASE SHOWS BOTH POLYSYNTHETIC TWINNING AND ZONING. THE GROUNDMASS MINERALS ARE LIOUIDOUS CRYSTALS OR MICHOLITE. NOT DEVITRIFICATION PRODUCTS.
optics indicate
OLIVINE - FO LESS THAN 80. PERHAPS ABOUT 70.
PLAGIOCLASE - AN ABOUT 65
GLASS - H GREATER THAN 1.57.
SAMPLENO. 12057.23 BRECCIACHIP WILCOX
this appears to be a breccia of several generations of clasts. healed and REMELTED TO VARYING EXTENTS. PREDOMINANT FRAGMENTS ARE CALCIC PLAGICCLASE. CLINOPYROXENE AND AGGREGATES OF SAME. IN SERIAL SIZE DISTRIBUTICN FROM ABOUT 1.5 MM DO甘N TO IRRESOLVABLE PARTICLES.

ONE PROMINENT CLAST ABOUT 4 MM DIANETER IS MADE UP CHIEFLY OF CALCIC plagioCLASE FRAGMENTS. IN THIS MASS IS ONE ROUNDED FRAGMENT OF SANIDINE ABOUT 0. 3 mM DIAMETER. IT HAS LOW NEGATIVE RELIEF. 2V NEGATIVE. ABOUT 20 DEGREES. AND LOW BI REFRINGENCE. ONE GOOD CLEAVAGE SHOWN. POSSIBLY a SECOND CLEAVAGE PRESENT. DEVELOPING IN THE PERIPHERY ARE SMALL MASSES OF HIGHER POSITIVE RELIEF AND higher birefringence than the host sanidine. and these resemble the preDOMINANT CALCIC PLAGIOCLASE OF THE ROCK. anOTHER CRYSTAL FRAGMENT NEAR EDGE OF SLIDE SHOWS MODERATE NEGATIVE RELIEF. LOW BIREFRINGENCE. FAR OFF CENTER FIGURE POSSIBLY NEGATIVE SIGN. (THE MODERATE NEGATIVE RELIEF ARGUES AGAINST SANIDINE FOR THIS FRAGMENTJ. ADDENDUM TO NOTE OF 12/9/69 ON THIS THIN SECTION.
in the same breccia fragment as the sanidine referred to already are several CLOTS OF STRONG NEGATIVE RELIEF. VERY LOW BIREFRINGENT MATERIAL CCRISTOBALITE/ TRIDYMITEJ IN WHICH ARE SET NUMEROUS STUBBY CRYSTALS OF POSITIVE RELIEF (PYROXENE). THESE MAY BE VUG FILLINGS. BUT THE ARRANGEMENT OF PYROXENE CRYSTALS IN SOME CLOTS IS REMINISCENT OF THAT IN GHOSTS OF QUARTZ XENOCRYSTS in some basalts.
FURTHER ADDENDUM. IN REGARD TO THE SILICA-RICH CLOTS MENTIONED IN MY NOTE OF DECEMBER 11. A FURTHER POSSIBLE ORIGIN TO BE CONSIDERED. AND ONE WHICH SEEMS mORE PLAUSIBLE than those 2 previously suggested. would be that they are RELICS OF SILICA-RICH GLASS FRAGMENTS IN THE BRECCIA. SUCH GLASS COULD liguify readily on reheating of the rock white the predominant calcic plagioClase and the scattered olivine afd pyroxene fragments remalned essentially UNAFFECTED. SUBSEQUENT SLOW COOLING YOULD RESULT IN THE FELDSPAR-TRIDYMITE MASSES OBSERVED.

SAMPLE NO. 12057. 23
CHAO
TRIANGULAR-SHAPED THIN SECTION COVERED. IT IS A BRECCIA EMBEDDED IN A RECRYSTALLIZED VESICULATED MELT.

VESICULAR DARK FINE-GRAINED GROUNDMASS WITH NUMEROUS FELDSPAR CHIPS BOTH ANGULAR AND ROUNDED. AND A LARGER FRAGMENT OF BRECCIA THAT IS RICH IN FELDSPAR. A FEW SMALLER ROUNDED BRECCIA FRAGMENTS ALSO INCLUDED. THE ABUNDANCE OF FELD-SPAR-RICH ROCK FRAGMENTS IS YGRTH NOTING.

THE VESICULAR DARK GROUNDMASS CONSISTS OF SMALL LATH-SHAPED CRYSTALS OF LOW BIREFRINGENCE PROBABLY FELDSPAR AND FINE-GRAINED MAT OF PROBABLY PYROXENE.

A FEW VESICLES 0.6 TO 1.4 MM ACROSS SPACED 1 TO ABOUT 3 MM APART. CHIP SIZE FROM ABOUT 20 MICRO UNITS TO 1.5 MM THE LARGE FRAGMENT IS \(5 \times 5\) MM. SEE MENTION OF SANIDINE (QUESTION) IN THIS BRECCIA BY WILCOX.

THE BRECCIA SEEMS EMBEDDED IN A VESICULAR GLASS WHICH HAS RECRYSTALLIZED. THE THIN LAYER OF GLASS AROUNG THE LARGE BRECCIA (OLDJ FRAGMENT IS A COHMON OCCURRENCE AMONG IMPACT-PRODUCED BRECCIAS.

THE ROUNDING OF SCME OF THE FRAGMENTS MAY HAVE BEEN PRODUCED PRIOR TO INCLUSION IN THE MELT SINCE SMALLER FRAGNENTS APPEAR TO RETAIN SHARP ANGULAR SHAPE.
the abundance cf gragments in the recrystallized glass is perhaps unusual. ONE TWINNED PLAGIOCLASE FRAGMENT SHOY LAMELLAR MICROSTRUCTURE OF PROBABLE SHOCK ORIGIN.

THE BRECCIA IS PROBABLY AN IMPACT BRECCIA. THE RECRYSTALLIZED GLASS : PROBABLY PRODUCED BY IMPACT. I FIND IT OIFFICULT TO ABSOLUTELY RULE CUT THi POSSIBILITY THAT SUCH PJLVERIZED ROCK CHIPS COULD NOT HAVE BEEN CAUGHT IN a melt MAGMATIC ORIGIN.

SAMPLE 12057.23 OPAOUES ROBIN BRETT
ROCK IS BRECCIA AND CONTAINS UNCOMMONLY LO甘 OPAOUE CONTENT. A FEW ILMENITE grains and metal blebs reminisient of metal in impactites.

SAMPLE NO. 12057.23 THIN SECTION FRONDEL
A POLYMICT MICROBRECCIA. ON THE WHOLE THE ROCK APPEARS TO BE MORE FELDSPATHIC THAN THE APOLLO \(1!\) miCROBRECCIAS. THE LATTER ALSO CONTAINED MORE LITHIC FRAGMENTS OF IGNEOUS ROCK TYPES INCLUDING BOTH GABBROIC AND BASALTIC TYPES AND also more glass. a fragment of a curious rock type was observed that contained ELONGATE TINY FELDSPAR CRYSTALS AND THAT MAY BE A DEVITRIFIED GLASS.
W. R. GREENWOOD DECEMBER 6. 1969 THIN SECTION 12057.23 VESICULAR CRYSTAL AND ROCK FRAGMENT PYROCLASTIC ROCK. SIMILAR IN APPEARANCE TO IMPACTITE FROM METEOR CRATER. ARIZONA.
THE MATRIX (A) OF THE ROCK IS A FINE INTERGROWTH OF CRYSTALS AND BRUWN GLASS PROBABLY PYROXENE, PLAGIOCLASE AND ILMENITE. THIS MATRIX VARIES IN GRAIN SIZE FROM ONE EDGE AT \(100 U\) OR SO TO THE INTERIOR AT CSOU.
PYROXENE FRAGMENTS COLIVINE MAY ALSO BE PRESENT / INSPECTION TOO BRIEF TO TELL\} CONSTITUTE ABOUT 20 TO 30 PERCENT OF THE FRAGMENTS IN THE MATRIX (A). PLAGIOClase fragments dominate. the plagioclase and pyroxene laths which are crystalLIZED OUT OF THE MATRIX (A) FORM AN INTERGROWTH WHICH IS SIMILAR TO THE MATRIX OF IMPACTITE FROM METEOR CRATER. ARIZ. MATRIX (A) INCLUDES A LARGE UNIT OF MATRIX (B) COMPOSED OF PLAGIOCLASE CRYSTAL FRAGMENTS AND ALMOST DEVOID OF PYROXENE OR OLIV!NE. MATRIX (B) CONTAINS A ROCK FRAGMENT OF ANORTHOSITE. MATRIX (B) ALSO CONTAINS ONE LARGE ROUNDED CPYSTAL FRAGMENT WHICH WILEOX indicates has paradine gptics. a large plagioclase crystal fragment in matrix (B) ACTS AS a NUCLEATION POINT FOR PLAGIOCLASE CRYSTALS WHICH GROY JUT INTO THE MATRIX. NO PYROXENE WAS OBSERVED IN A BRIEF INSPECTION OE THE CRYSTALS GROWING IN THE MATRIX (B). ALSO THE MATRIY. (B) LACKS THE BROWN COLOR OF MATRIX (a). the laree plagioclase CRystal has been sheared and granulated in place in MATRIX (B), SUGGESTING THAT MATRIX (B) WAS BROKEN UP BEFORE INCLUSION IN MATRIX (A). NO GLASS SPHERES OR GLASS FRAGMENTS WERE SEEN IN EITHER MATRIX (A) OR (B). ONE LARGE IRREGULAR VESICLE IN MATRIX (A) (MATRIX (B) NOT VESICULATED) IS FILLED WITH LOOSE LUNAR SOIL INCLUDING BROZN GLASS SPHERES.
the sanadine crystal fragment may be related to a last stage differentiate of THE ANORTHOSITE MAGMA YHICH may have previously been Differentiated from the CUMULATE TEXTURED GABBRO (12057.21).

SAMPLE NO. 12057.23
SMITH
THIN SECTION EXAMINATION OF THIS ROCK INDICATES THAT THE CHIP IS NOT REPRESENTATIVE OF The bhole sample. the rock represented by the thin section is a CURIOUS MIXTURE OF XENOCRYSTS AND ROCK FRAGMENTS IN A GROUNDMASS OF VESICULATED GLASSY ROCK THAT YAS CRYSTALLIZING TINY CRYSTALS OF PLAGIOClase and pyroxene YHEN OUEPSCHED.
many of the plagioclase xenocrysts shek melting relations yith the groundmass GLASS AND IN SOME THE FELDSPAR GLASS SHO甘S RECRYSTALLIZATIONS PRODUCTS.
THE ROCK SEEMS CLEARLY A PRODUCT OF SOME KINO OF BRECCIATION. FUSION. VESICULATION. PARTIAL RECRYSTALLIZATION. ASD QUENCHING IN THAT ORDER OR PERHAPS MIXING OF FUSED AND BRECCIATED MATERIAL. FURTHER PARTIAL FUSIUN OF FELOSPIAR AND PROBABLY PYROXENE. VESICULATION. PARTIAL RECRYSTALLIZATIGN AND OUENCHING. the general felations seeit in this rock are atypical of volcaric phenomena although it prozably cainivot be ruled out and are more suggestive of cohplex IMPACT HISTORY.

Figure A-52.- Sample 12057-11 (NASA-S-69-61405).

SAMPLE NO. 12059
FINES AND A ROCK CHIP - SGEEPINGS FROM BIO PREP.
THE FOLLOWING EXPERIMENT WAS CONDUCTED ON THIS SAMPLE total Carbon analysis

\section*{SAMPLE 12060}

SAMPLE NU . 12060 PCTL C. FRONDEL DESCRIPTION OF FINES FROM TOTE BAG. THE FINES CONSIST OF PYROXENE ABOUT 40 PERCENT. ANORTHITE ABOUT 30 PERCENT. OLIVINE ABOUT 10 PERCENT OR LESS. GLASS ABOUT 20 PERCENT. LESS THAN 1 PERCENT tRIDYMITE IS PRESENT. THE AMOUNT OF GLASS IS MUCH LESS THAN IN THE FINES FROM THE APOLLO 11 SITE. THE GLASS RANGES FROM COLORLESS THROUGH PALE GREEN. PaLE YELLOW. TAN. BROYN AND DARK RED BROGN. ON THE WHOLE. THE GLASS AND ALSO THE BULK FINES are somewhat lighter in color than in the apollo 11 material. the pale YELLOW GLASS HAS AN INDEX OF REFRACTION BELOd 1.640 THE TAN AND DARKER COLORED GLASS IS OVER 1.640. THE COLORLESS GLASS IS NOT ABUNDANT. SOME GRAINS ARE JUST BELOW 1.570. BUT MOSTLY THE INDEX IS SOMEWHAT OVER 1.570. FELDSPAR GLASS SEEMS TO BE MUCH LESS ABUNDANT THAN IN THE APOLLO 11 SAMPLE. GLASS SPheres. DUKBBELLS. RODS. AND TEARDROPS ARE PRESENT IN ADDITION TO ANGULAR FRAGMENTS. AN UNIDENTIFIED DARK BROßN MINERAL. NOT PLEOCHROIC. WITH INDICES BELOW 1.570 WAS NOTED. MANY OF THE MINERAL GRAINS ARE WELL ROUNDED. AS IN A DETRITAL SAND OR DUNE SAND (SEE PHOTOS).
the following experiment was conoucted on this sample

DIMENSIONS \(2 \times 2 \times 1 / 2 \mathrm{CM}\)
THIS IS A HOLOCRYSTALLINE MEDIUM FINE GRAINED MICROGASQROIC ROCK YITH OLIVINE. SIMILAR TO APOLLO 11 TYPE B WITH PROBABLY LESSER AMOUNT OF ILMENITE. THE TYPE OF BROZN PYROXEIVE APPEARS TO BE THE SANE AUGITIC CLINOPYFOXENE OF APGLLO I! SAMPLES IN COLOR APD HABIT.. FLAT AND SLIGHTLY CONVEX. DISK SHAPED. SPECKLED BRO甘NISH GREY. SUBOPHITIC TO GRANULAR TEXTURE. HOLOCRYSTALLINE, VESICLES pRESENT. the flat Surzface is a fracture surface several glass litied pits on CORVEX SIDE SURROURDED BY A HALO OF MILKY EHITE MATERIAL. FRACTURED FELDSPAR。 200 TO 500 U IN DIAi:ETER. Oit THE CONVEX. ROUNDED SIDE NOT Ois THE FLAT FRACTURED SIDE. AVERAGE GRAIN SIZE IS ABOUT 2 TO 300 MICRONS. LARGEST CRYSTAL ABOUT 1.5 MM. LARGER CRYSTALS PROBABLY PLAGIOCLASE AND ILMENITE. FRACTURED MILKY plagioclase on rounded convex surface. mineralogy. l. clear platy lath SHAPED TO IRREGULAR SHAPED CRYSTALS WHICH ARE PROBABLY PLAGIOCLASE. ABOUT 45 TO 50 PERCENT. PROBABLY POIKILITIC. 2. PALE BROWN TO CLEAR BROWN STUBBY PRISMATIC TO IRREGULAR CRYSTALS. PROBABLY PYROXENE SIMILAR TO CLINOPYROXENE OF APOLLO 11. ABOUT 40 TO 45 PERCENT. 3. BLACK PLATY AND HIGHLY REFLECTING MINERAL YITH LUSTROUS FRACTURES. PROBABLY ILMENITE 5 TO 10 PEREENT. 4. GREENISH YELLOW MINERAL IN SMALL AMOU!JTS ABOUT 2 TO 300 MICRONS ACROSS AND OCCURRING IN PATCHES. PROBABLY OLIVINE.

SAMPLE NO. 12061 SECOND LARGEST CHIP DIMENSIONS \(2 \times 1 \times 0.6\) CM CHAO ELONGATED YITH TRIANGULAR CROSS SECTION. SPECNLED BROWNISH GREY. SIMILAR TO the largest chip. vuggy IrRegular cavities exist with tabular plagioclase AND STUBBY PYROXENE PROTRUDING INTO THEM. THEY SOMETIMES COALESCE TO FORM OPENINGS 2 TO 3 MM IN LENGTH. ROUND HEMISPHERIC 1 MM IN DIAMETER. HAYE BEEN noted as surface features. there is the suggestion the surface area apound the PITS Which are as much as 1 mm in clameter. average crystal size is again about 2 TO 300 MICRONS. LONG PLATY CRYSTALS OVER 1 MM IN LENGTH HAVE BEEN KOTED. mineralogy. Quite similar to the mineralogy noted in the previous chip. preOOMINANTLY CLEAR PLATY PLAGIOCLASE FELDSPAR. BROWN CLINOPYROXENE. AND PLATY black ilmenite. accessory olivine is also present.

SAMPLE NO. \(12061 /\) THIRO LARGET CHIP DIMENSIONS \(1 \times 1 \times 0.4\) CM CHAO flat with some fracturing. also speckled brownish grey. similar to the LARGEST CHIP. ABUNDANT VESICLES. AT TIMES THEY COALESCE TO 1 TO 1.5 mm in LENGTH. IRREGULAR VUGS ARE AGAIN PRESENT UITH PRISMATIC AND PLATY BROKN PYROXENES ALONG WITH CLEAR PLATY PLAGIOCLASE IN THEM. NO PITS ARE OBVIOUS AND SO SUSPECTEO TO BE AN INTERIOR CHIP. VELL FORMED SHORT PRISMATIC PYROXENE CRYSTALS ARE PRESENT. AVERAGE GRAIN SIZE OF THE CRYSTALS IS ABOUT 100 TO 200 mICRONS. LARGE CRYSTALS ARE AS MUCH AS 1 MM. mINERALOGY. A LARGE GREEN YELLOW OLIVINE CRYSTAL ABOUT 0.8 MM IN DIAMETER WAS NOTED. OLIVINE AGAIN EXISTS AS AN ACCESSORY MINERAL. MINERALOGY IS AGAIN SIMILAR TO THAT OF THE LARGEST CHIP.

SAMPLE NO. \(12061 / F O U R T H\) LARGEST CHIP DIMENSIONS \(1 \times 0.8 \times 0.3 \mathrm{CM}\). CHAO flaf oblong shaped fragment. Similar to other chips. Similar texture. long lathLIKE plagioclase crystals aeout 1 mi in length appear poikilitic. no pits NOTED. AVERAGE GRAIN SIZE IS ABOUT 2 TO 300 MICRONS. MINERALOGY. SIMILAR. SAMPLE NO. 120612 SMALLEST CHIPS DIMEHSICNS ABOUT \(0.8 \times\) AGOUT \(0.7 \times\) ABOUT 0.3 ChaO COLOR SAME AS OTHERS. tEXTURE SAME AS OTHERS. VUGGY AND SIMILAR. ONE SURFACE PIT NOTED. LONG PLATY PLAGIOCLASE CRYSTALS OCCUR ABOUT 1 MM IN LENGTH. MINERALOGY. SIMILAR TO OTHER CHIPS.

Figure A-53. - Sample 12061 (NASA-S-69-61659).

SAMPLE NO. 12062 VEIGHT 787.7 GRAMS DIMENSICNS \(12 \times 8 \times 4\) CM SMITH this rock has the apfroximate shafe of an irregular flattened half deme. with PARTLY CONCAVE BOTTOM. ANGULAR BROKEN SIDE. A:ID RQUNDED TOP. COLOR IS MEDIUM GRAY TO LIGHT GRAY VITH WHITISH MOTTLING. SOHE OF THE WHITISH AREAS aRE haloes surround ing glass pits cnot abuirdant on this specimenj. other vhitish areas are simply spots of chalky feldopar that remaln after glass pits have ERODED AHAY. PART OF THE CONCAVE BOTTOH AND A PORTION OF THE BRCKEN SIDE are DARKER AND LESS MOTTLED ThAN THE REMAINDER OF THE ROCK AND MAY REPRESENT a BURIED OR OTHERHISE PROTECTED PART OF THE ROCK ON THE LUNAR SURFACE. CONCENTRIC FRACTURES SUBPARALLEL TO THE RGCK SURFACE APPEAR ON PART OF THE TOP AND BORKEN SIDE AiSD RESEMBLE EXFOLIATION FRACTURES. SOME OF THESE FRACTURES SEEM TO PENETRATE DEEPLY. R RADIAL SET OF FRACTURES CENTER OF THE EXFOLIATION SPHEROID AND SUGGEST THAT THE EHOLE SYSTEM IS IHPACT INDUCED.
Small vesiclies afd vugs are present but not abundant at viewifg scales. ONE SMOOTH YALLED VESICLE (APPROXIMATELY 3 TO \& MM) APPEARS ON THE BROKEN SIDE AND SHOWS BRIGHTLY REFLECTING CRYSTAL FACES OF FELDSPAR. TEXTURE IS BEST DESCRIBED AS OPHITIC TO SUBOPHITIC. WITH LARGER CRYSTALS IN VUGGY ARERS.
major minerals are cinnamon red to broypl pyroxente. feldospar. opaoues and olivine THE OLIVINE IS SPAR - BUT OCCURS IN LARGE CUP TO 7 MMJ CRYSTAL AGGREGATES. much of the concave eottoia side has fine textured hackly surface with strongly ADHERING DUST AAD SCATTEFEC AREAS OF GLASS SPLASH NOT FOUND ON TOP SURFACE. a FEW GLASS LIAED PITS OCCUR ON THE OUTER PERIPHERY OF THE CONCAVITY, BUT NONE MERE SOUND IN THE CENTRAL PART UITHIN AN AREA ABCUT 3.3 CM IN DIAMETER. IN the center of the concave surface is a suboued flat cone or mound about 1.2 Cm IN GIAMETER AND SEVERAL MM HIGH THAT FORMS THE FOCUS FOR A SUBTLE RADIAL FRACTURE SET.
It seems probably that this concave surface is actually an impact crater and THE CONCENTRIC AHD RADIAL FRaCTURE PATTERN ON ROCK'S OPPOSITE SIDE IS genetically related.
at least cne otrien lafge rock in the apgllo 12 return has one deep concave side (first rock loúiied at in f201). perhaps these ccincave sides have similar ORIGINS.
MORFHOLOGY. MACROSCGPIC
FLAT HALF DCUÍE. BOTTC:I SIDE PARTLY CGICAVE. EROKEN SIDE OF DOHE AMGULAR.
REMAINDER OF TOP RCU::DED. NEDIUIA GRAY TO LIGHT GRAY AIVD LHITISH HOITLED.
PROBABLY SUBOPHITIC TO OPHITIC. MEDIUM GRAINED LUNAR ROCK. COARSE TYPE A. NO LINEATIONS OBVIOUS. VESICLES FRESENT BUT NOT ABUNDANT AT THIS SCALE OF VIEWING. ONE LARGE SMOOTH WALLED VESICLE ON BROKEN SIDE (APPROXIMATELY 3 MM) CONTAINS BRIGHTLY REFLECTING CRYSTAL FACES. FRACTURES PRESENT BUT NOT ABUNOANT. ONE FRACTURE OF DOMICAL TOP AND BROKEN SIDE SHOWS CONCENTRIC EXFOLIATION FRACTURES. these seem to penetrate deeply into rock and are rssociated vith a radiai set CENTERING ON THE EXFOLIATION SPHEROID. NO SPLASHES NOTED ON TOP. SURFACE PITS PRESENT QVER DOMAL TOP AND SIDES BIJT SEEMINGLY NOO ABUNDANOH
APPROXIMATE MODES. OLIVINE LESS THAN 1 PERCENT
PYROXENE 50 PERCENT
FELDSPAR 40 PERCENT
opaque less than 10 PERCENT
pyñoxenes approximately equant
FELDSPAR LATH LIKE
opagues tabular to platy.
CRYSTALS LARGER NEAR VUGS. NO OBVIOUS ALTERATION.
terrestrial analogue. fine grained diabasic olivine bearing basalt.
SAMPLENO. 12062 VEIGHT 737.7 GRAMS DIMENSION \(10 \times 6 \times 4\) CM HARMON THE GENERAL SHAPE OF THE ROCK IS THAT OF \(1 / 4\) OF A SPHERE OR RATHER AN ELLIPSOID SUBSEOUENTLY. SOME OF THE CORNERS AND EDGES OF THE ROCK APPEAR TO HAVE ERODED
abay. the rounded surface of the rock has beathered to an extent that it appears like a small scale exfoliation dome. the color of the rock is a light MEDIUM GREY WITH AREAS OF THE SURFACE COVERED WITH SPLOTCHES OF A YHITE CCLOR. IN TwO PLACES THESE WHITE AREAS ARE ASSOCIATED WITH IMPACT PITS IN THAT THEY are shattered areas surrounding the craters to about one ciater olameter out FROM THE CRATERS. THESE OTHEP. WHITE SPLOTCHES NOT ASSOCIATED WITH PITS ARE PROBably Shatter areas underlying pits that have since been eroded ayay. one very NICE VESICLE ABOUT 2 mM IN DIAmeter IS PRESENT ON ONE SUnface OF the rock. THIS ROCK SHOHS A MODERATE AMOUNT OF FRACTURES CHARACTERIZED BY THE EXFOLIATION features. the density of pirs and vesicles is very low. the cbottomb concave SURFACE OF THE ROCK IS ALSO a FRACTURE SURFACE AND APPEARS ALSO TO BE AN exfoliation feature. the (topj Convex surface of the rock also appears to have a Shatter crust that is lighrer in color than the fresh surfaces of the rock WHERE EXPOSED ALONG EXFOLIATICN FRACTURES. LATH SPADED MINERALS AND A MINERAL WITH a metallic luster are ogvious in ground mass on a macroscale.

NASA-S-69-60606

Figure A-55. - Sample 12063.

SAMPLE NO．12063．6 WEIGHT 4．5 GRAMS DIMENSIONS \(4.5 \times 3 \times 2\) CM FOSS （HAND SPECIMEN 12063 AND CHIP 12063.6 ］．THE ROEK IS IRREGULASLY SHAPED．SUB－ angular to subrounded．with several planar．subfarallel surfaces．and ene major CONCAVITY FORMED BY PLANAR FRACTURES（2．5 X 5 CM）．THE DIMENSICNS OF THE LONGEST．INTERMEDIATE AND SHORTEST AXES OF THE ROCK ARE 18 CM． 12 CM．AND 8 CM RESPECTIVELY．THE SHAPE IS ROUGHLy THAT OF A SMALL．PARTIALLY COLLAPSED FOOTBALL．
THE ROCK IS LIGHT TO MEDIUM GRAY IN COLOR．HITH MANY DARKER SPOTS CAUSED BY
 BOUNDED CONCAVITY SHOWS A SUBOPHITIC TO OPHITIC TEXTURE OF WHITE FELDSPAR LATHS INTERGRO甘N 甘ITH A BROWNISH GLASSY MINERAL．PROBABLY PYROXENE．
a Rather Striking feature of the rock is a planar zone of somewhat flattened VESICLES THAT INCLUDES THE LONG AND SHORT AXES OF THE ROCK．THE VESICLES ARE Flattened perpendicular to the zone and have an average long dimension of ABOUT 0．5 CM．THE REMAINDER OF THE ROCK IS RELATIVELY FREE FROM VESICLES． ALTHOUGH SOME SMALL（LESS THAN O．S CM）VUGGY CAVITIES ARE PRESENT THROUG：HOUT THE ROCK．
there appears to be one major fracture that coincides with the plane of VESICLES．A SET OF 3 OR 4 CLOSELY SPRCED FRACTURES CROPS OUT ON ONE SURFACE OF the rock．at an angle of about 30 degrees to the vesicle zene．one large cavity IN A CORNER OF THE ROEK IS BOUNDED SY PLANAR FRACTURES．AND ONE CORNER IS EXPOSEU BY a CONVEX OUTVARD SMALL FRACTURE．
THE ROCK EXHIBITS OX：E LARGE PATCH OF GLASS（G MM By 1 CM）That may be the BOTTOM OF A LARGE IMPACT PIT OR A GLASS SPLASH FROM ELSE甘HERE．THE THO MAJOR EXTERIOR SURFACES OF THE ROCK OTHER THAN THE SUBPARALLEL PLANAR SURFACES have ABUNDANT SMALL APPROXIHATELY 1 HM IMPRCT PITS．THE SUBPARALLEL PLANAR SURFACES ARE RELATIVELY FREE FROM PITS．THERE IS A DISTINCT tititish halo of CHALKY FELDSPAR ARGU！VD THE PITS AND AROU：UO THE GLASS PATCH．
THE ROCK IS AIJALOGGUS TO A TERRESTRIAL DIABASE OR FINE GRAINED GABSRC． THE CHIP has the shape of a rough hemisphere with one flattened side and a SLIGHTLY CONCAVE BASE．DIAMETER OF HEMISPHERE 4．5 CM．DIAMETER TO FLATtENED SIDE 3 CM．HEIGHT 2 CM．
THE CHIP IS LIGHT BROWNISH GRAY ON A FRESHLY BROKEN SURFACE AND SHOWS a SUB－ OPHITIC TEXTURE．THE ROCK CONTAINS SOME VUGS THAT APPEAR TO BE OF TWO TYPES． SOME ARE ANGULAR AND ABOUNDED BY CRYSTAL FACES OF PLAGIOCLASE FELDSPAR．OTHERS are more rounded and have crystals of feldospar．pyroxene．and ilmenite grobing INTO THEM．THE ILMENITE AND PYROXENE CRYSTALS SHOW GOOD CRYSTAL FACES IN THE VUGS．
the rock is made up of 1 1． 50 percent Glassy tabular crystals of plagioclase WITH AVERAGE SIZE 0．1 MM．2． 40 PERCENT LIGHT BROWN TO AMEER EQUANT CRYSTALS OF PYROXENE WITH AVERAGE SIZE 0.01 mM．3． 5 PERCENT BLACK mETALLIC blade like crystals of Ilmenite with average size o． 02 mm．4．less than 5 per CENT PALE GREEN GLASSY CRYSTALS OF OLIVINE WITH aVERAGE SIZE＇j． 9 mm． ROCK HAS A DEFINITE PORPHYRITIC TEXTURE OF OLIVINE PHENOCRYSTS IN A SUBOPHITIC GROUNDMASS OF PLAGIOCLASE．PYROXENE AND ILMENITE．

someone should measure the made -
REMARKS - THIS IS A PORPHYRITIC. OLIVINE BEARING (LESS THAN 1 PERCENT) Ilmenite basalt with a unioue texture. the surparallel phenocpysts suegest floy. the texture should be of interest to the petrographers. the amount of ILMENITE IS LESS THAN APOLLO 11 RCCKS. THIS TEXTURE IS UNIOUE TO APOLLO 12. NOT STUDIED WITH REFLECTED LIGHT.

SAMPLE NO. 12065.7 A THIN ૬ECTION OF A TOTE BAG SARIPLE HARMON A HOLOCRYSTALLINE ROCK WITH A GENERALLY APHANITIC GROUNDMASS AND PYROXENE PHENOCRYSTS. FOUR BASIC MINERAL PHASES ARE PRESENT. A CLINOFYROXENE. A plagioclase feldspar. an opaque oxide and olivine.
1. CLINOPYROXENE. OCCUPS AS BOTH PHENJCRYSTS AND GROUNDMASS MATERIAL.

THE LARGER GRAINS Riñge up TO 2 mM IN GRAIN SIZE. THESE PHENOCRYSTS ARE MOSTLY EUHEDRAL GRAINS THAT RESORPTION OR REMELTING EFFECTS AS SHOYN BY THE FACT THAT CRYSTAL BOUNUARIES ARE IRREGULAR AND MOST CROSS SECTIONS PRESENT SHOW ZONING. IN THE GROUNDiAASS IT OCCURS AS SLONGATE RADIATING CRYSTAL AGGREGATES. INTER GROWN WITH PLAGIOCLASE FELDSPAR. a TEXTURE INDICATIVE OF RAPID COOLING. MANY OF THE PHEHOCRYSTS OF CLINOPYROXENE SHCE A ZONED CROSS SECTION WITH THESE GROUNDMASS AGGREGATES OF CLINOPYROXENE AND FELDSPAR IN THE CENTER. PHENOCRYSTS ARE PIGEONITE.
2. PLAGIOCLASE FELDSPAR. OCCURS AS GROUNDMASS MATERIAL IN THO FORMS. A) STUBBY. LATH SPADED GRAINS. RECTANGULAR IN HABIT AND BJ RADIATING ELONGATE GRAINS INTERGRO甘N WITH THE A CLINOPYROXENE OF
the same hablt.
3. OPAQUE OXIDE. OCCURS AS PLATY AND IRREGULARLY SHAPED GRAINS. MOST GRAINS CUT ACROSS GRAIKS OF ALL OTHER PHASES. BUT SOME OF THE LARGER GRAINS TOTALLY ENCLOSE SỦiE SHALL FE:LDSPAR GRA!NS. OPAQUES APPEAR TO BE MORE AEUNDANT IN THIS ROCK than any otiter osserved to onte.
4. OLIVINE. OCCURS AS LARG? GRAINS UP TO I MM IN GRAIN SIZE. MOST GRaINS ENCLCSE SMALLER GRAINS GF THE OPAOLIE.

NASA-S-69-61748

Figure A-59. - Sample 12072.

SAMPLE 12073
SAMPLE NO. DIMENSIONS \(10 \times 6 \times 6 \mathrm{CM}\) LOFGREN
NO VESICLES EXCEPT IN FRAGMENTS. FEW FRACTURES. RANDOM FRACTURE ORIENTATION.
MUCH GLASS ON SURFACE.
IS A. MEDIUM GRAY RECTANGULAR mODERATELY ROUNDED BRECCIA OR TYPE C ROCK. THE COLOR OF A FRESHLY BROKEN SURFACE IS ONLY SLIGHTLY LIGHTER THAN ORIGINAL SURFACE the surface is pitted and has glass coating. the fits are glass lined and SHALLOW. THEY RESEMBLE THE PYTS ON CRYSTALLINE RX MORE THAN THE PITS ON the bRECCIAS IN the apollo 11 ROCKS. SOME EVEN have Slight haloes. the surface DENSITY IS REASONABLY EVEN OVER THE SURFACE APPRCXIMATE 2 TO 3 CM2. THE ROCK has large areas of vesicular glass splasi that appears to be a coating. another area of glass separate from the large splash has more the appearance of eeaded SOLDER WITH RADIATING FRACTURES AND RIDGES FROM THE GLASS. THE LARGE GLASS COATING SHOULD be COLLECTED AND PROBED. THERE ARE NO I INEATIONS AND FRACTURES are mogerately abundant and randomly orientaied.
THIS BRECCIA IS HARDER THAN THE AVERAGE APSLLO 11 BRECCIA AND MOST SIMILAR TO APOLLO 11 BRECCIA 1005 WHICH APPEARS TO BE BAKED. THE CRYSTALLINE FRAGMENTS are mostly vesicular and fine grained. some are coarse grained and vuggy. fey OLIVI:IE PICH FRAGMENTS WERE Oß̉SERVĒD.
ROCKS 12073 AND 12074 ARE PARTS OF THE SAME ROCK. I RECOMMEND THiAT WE COMBINë the numbers to 12073 and make the pieces one rock number.

\section*{APPENDIX B}

\section*{TOTAL CARBON AND ORGANIC ANALYSES DATA SHEETS}

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Control Sample Number: 1200
2. Weight: 100 grams
3. Sample Description (from original description)

Rock type: Ottawa sand (Ames Research Center (ARC))
Physical appearance: Control for sand monitor in Biological Preparation Laboratory (Bioprep) (from ARC); analyzed as supplied by ARC
4. Sample History

Return container:
Schematic processing diagram: ARC—GAL—GAL glove box
Storage container sequence: Glass jar
Processing comments: The sand was stored in a glass jar with a plastic cap. The reagent-grade Ottawa sand was acid washed and fired by the supplier at \(1000^{\circ} \mathrm{C}\) for 30 hours at ARC and shipped to the LRL in a clean glass jar.

Control sample number: Not applicable
5. Total Carbon Analysis Results

Run no. Sample weight, g Carbon content, ppm
1
1. 0082
\(7 \pm 2\)
6. Organic Analysis Results

Maximum total ionization: \(2.6 \times 10^{4}\)
Total ionization: \(3.3 \times 10^{5}\)
Estimated organic content (total of indigenous and contamination): <0.1 ppm
7. Remarks

Early spectra data indicate some general mass spectra as seen in the Bioprep monitor.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Control Sample Number: 1201
(originally B108)
3. Sample Description (from original description)

Rock type: Ottawa sand (ARC)
Physical appearance: Bioprep cabinet monitor
4. Sample History

Return container:
Schematic processing diagram: ARC—GAL——Bioprep-GAL glove box
Storage container sequence: Glass jar—Teflon bag-Quick-seal canWasserburg container

Processing comments: Control sample 1201 was exposed to the Bioprep cabinet atmosphere for 5 hours during the early stages of the D-ALSRC processing. The sample was sterilized into the Bioprep in a Teflon bag at \(160^{\circ} \mathrm{C}\).

Control sample number: 1200
5. Total Carbon Analysis Results

Run no. Sample weight, g Carbon content, ppm
1
0.4618
\(4 \pm 2\)
6. Organic Analysis Results

Maximum total ionization: \(3.8 \times 10^{4}\)
Total ionization: \(5.2 \times 10^{5}\)
Estimated organic content (total of indigenous and contamination): <0.1 ppm
7. Remarks

The spectra were characterized by low \(\mathrm{CO}_{2}\) evolution compared to the lunar samples. Material of \(\mathrm{m} / \mathrm{e} 58\) and other low-weight materials were the obvious contaminants ( \(\mathrm{m} / \mathrm{e} 84\) and 86 is methyl chloride from sample handling). The higher weight materials seen in some of the lunar samples (deep core) were not obvious in this blank. The mass spectrometer scans for control sample 1201 are shown in figure \(\mathrm{B}-1\).

Figure B-1.- Mass spectrometer scans for control sample 1201.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Control Sample Number: 1210 2. Weight: 250 grams
3. Sample Description (from original description)

Rock type: Ottawa sand (MSC)
Physical appearance: Control for the sand monitor in the F201 vacuum system; analyzed after cleaning.
4. Sample History

Return container:
Schematic processing diagram: Washed-dried at \(110^{\circ} \mathrm{C}\)-fired at \(1000^{\circ} \mathrm{C}\) sealed in Teflon bag-GAL glove box

Storage container sequence: Teflon bag
Processing comments: None
Control sample number: Not applicable

Run no. Sample weight, g Carbon content, ppm
1
1. 0001
\(18 \pm 3\)
6. Organic Analysis Results

Maximum total ionization: \(7.5 \times 10^{4}\)
Total ionization: \(1.5 \times 10^{6}\)
Estimated organic content (total indigenous and contamination): <0.1 ppm
7. Remarks: None

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Control Sample Number: 1211
2. Weight:
3. Sample Description (from original description)

Rock type: Ottawa sand (MSC)
Physical appearance: F20:l system monitor
4. Sample History

Return container:
Schematic processing diagram: GAL-F201 chamber-GAL glove box
Storage container sequence: Teflon bag-bolt-top can
Processing comments: The Ottawa sand was washed in water, dried overnight at \(110^{\circ} \mathrm{C}\), and then fired at \(1000^{\circ} \mathrm{C}\) in a muffle furnace for 24 hours in the GAL. The sand was sealed in a Teflon bag for approximately 2 weeks before being loaded into a bolt-top can for transfer into the F201 chamber. The sand was transferred into the bolt-top can on a clean bench. The sample was exposed to the F201 vacuum chamber beginning on November 29, 1969 (0800), and was sampled on December 10, 1969 (0930). During this time, the F201 chamber was backfilled with N three times for a total of approximately 60 hours.

Control sample number: 1.210
5. Total Carbon Analysis Results: Not available
6. Organic Analysis Results

Maximum total ionization: \(7.6 \times 10^{4}\)
Total ionization: \(2.3 \times 10^{6}\)
Estimated organic content (total of indigenous and contamination): 0.1 ppm
7. Remarks: None

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12003-1
2. Weight: 300 grams
3. Sample Description (from original description)

Rock type: D
Physical appearance: Chips and loose material from S-ALSRC
4. Sample History

Return container: S-ALSRC
Schematic processing diagram: S-ALSRC—F201 chamber——Bioprep—GAL glove box

Storage container sequence: S-ALSRC—bolt-top can—Wasserburg container
Processing comments: This material was collected from the floor of the F201 chamber and from the S-ALSRC York-mesh packing. The sample was exposed in the F201 chamber for 3 days (approximately 70 hours), stored in a bolt-top can, transferred to Bioprep, and sampled for organic analysis within a few minutes after being opened in Bioprep.

Control sample numbers: 1201, 1202, 1211
5. Total Carbon Analysis Results

Run no. Sample weight, g
0.1571
. 1128
. 1480
. 1605

Carbon content. ppm
\(185 \pm 20\)
\(195 \pm 25\)
\(120 \pm 10\)
\(200 \pm 10\)
6. Organic Analysis Results

Maximum total ionization: \(1.2 \times 10^{5}\)
Total ionization: \(4.4 \times 10^{6}\)
Estimated organic content (total of indigenous and contamination): 0.3 ppm
7. Remarks

Most of the ion current was due to previously recognized contaminants. This sample was one of the few samples that displayed m/e 78 and 91 as pyrolysis products, a common occurrence in the Apollo 11 preliminary analysis. The additional handling is probably reflected in the higher total C found in this sample relative to other Apollo 12 samples. The mass spectrometer scans for sample 12003-1 are shown in figure B-2.

Figure B-2. - Mass spectrometer scans for sample 12003-1.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12024-7
2. Weight: 100 grams
3. Sample Description (from original description)

Rock type: GASC
Physical appearance: Fines
4. Sample History

Return container: GASC
Schematic processing diagram: D-ALSRC—Bioprep —GAL glove box
Storage container sequence: GASC-glass vial
Processing comments: The GASC was not opened until it had been sterilized and transferred to the GAL. It was first punctured on the gas-extraction table. The estimated pressure at the time of puncture was 11 torr. Analysis of the gases indicated that leakage had occurred. The GASC then was valved off, transferred to the glove box, and opened. A total of 600 milligrams of fines material was removed from the GASC and stored in a chromic-acid-cleaned glass vial approximately 30 minutes after opening.

Control sample number: 1202
5. Total Carbon Analysis Results

Run no. Sample weight, g Carbon content, ppm 1
0.1395

115
6. Organic Analysis Results

Maximum total ionization: \(5.1 \times 10^{4}\left(1.1 \times 10^{5}\right.\) second run)
Total ionization: \(7.6 \times 10^{5}\left(3.0 \times 10^{6}\right.\) second run)
Estimated organic content (total of indigenous and contamination): 0.3 ppm ( 0.3 ppm second run)
7. Remarks

Two runs were made with very similar results. The higher weight material may be due to exposure to the plastic bottle cap when the Teflon liner developed a crack. The CO and \(\mathrm{CO}_{2}\) evolution was very high. The mass spectrometer scans for sample 12024-7 are shown in figure B-3 for the first run and in figure B-4 for the second run.

Figure B-3. - Mass spectrometer scans for sample 12024-7, run 1.

\]
(

Figure B-4. - Mass spectrometer scans for sample 12024-7, run 2.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12026-1 2. Weight: 54.2 grams
3. Sample Description (from original description)

Rock type: Core tube 2013
Physical appearance: Fines from 29-centimeter scale position
4. Sample History

Return container: Core tube - S-ALSRC
Schematic processing diagram: S-ALSRC—F201 chamber—Bioprep —GAL glove box

Storage container sequence: Core tube \(\longrightarrow\) Wasserburg container
Processing comments: The core tube was transferred to Bioprep unopened; it was open in Bioprep for approximately 24 hours before the sample for organic analy sis was taken.

Control sample numbers: 1.201 and 1202
5. Total Carbon Analysis Results

Run no. Sample weight, g Carbon content, ppm
1
0.018
\(44 \pm 25\)
6. Organic Analysis Results

Maximum total ionization: 6 . \(1 \times 10^{4}\)
Total ionization: \(1.1 \times 10^{6}\)
Estimated organic content (total of indigenous and contamination): 0.7 ppm

\section*{7. Remarks}

A small amount of low-molecular-weight material was present (notable m/e 64 \(\left(\mathrm{S}_{2}\right.\) or \(\left.\mathrm{SO}_{2}\right)\) ). Considerable CO and \(\mathrm{CO}_{2}\) were evolved. The mass plot of \(\mathrm{m} / \mathrm{e} 95\), which may be due to indigenous material or to a strongly adsorbed contaminant, was of special interest. The sample weight was too small for a good total C analysis. The mass spectrometer scans for sample 12026-1 are shown in figure B-5.

Figure B-5. - Mass spectrometer scans for sample 12026-1.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12026-2
2. Weight: 54.2 grams
3. Sample Description (from original description)

Rock type: Core tube 2013
Physical appearance: Fines from 21-centimeter scale position
4. Sample History

Return container: Core tube - S-ALSRC

Schematic processing diagram: S-ALSRC \(\longrightarrow\) F201 chamber \(\longrightarrow\) Bioprep \(\longrightarrow\) GAL glove box

Storage container sequence: Core tube \(\longrightarrow\) Wasserburg container
Processing comments: The processing comments are the same as for sample 12026-1.

Control sample numbers: 1201 and 1202
5. Total Carbon Analysis Results: Not available
6. Organic Analysis Results

Maximum total ionization: \(4 \times 10^{4}\left(3.3 \times 10^{4}\right.\), second run)
Total ionization: \(1.1 \times 10^{6}\left(4.3 \times 10^{5}\right.\), second run \()\)
Estimated organic content (total of indigenous and contamination): 0.5 ppm ( 0.1 ppm , second run)
7. Remarks

The second run was a re-run of the first run sample and was exposed to the atmosphere in the GAL glove box. Two points are important: (1) m/e 58 and other low-molecular-weight peaks; were present in both runs and (2) the CO and \(\mathrm{CO}_{2}\) evolution (compare 1209 and 1211 summation m/e 44 plots in figs. B-6 and B-7) slowly increased in the second run to approximately the level of the first run, indicating that CO and \(\mathrm{CO}_{2}\) are the result of the sample pyrolysis. The mass spectrometer scans for sample 12026-2 are shown in figure B-6 for the first run and in figure B-7 for the second run.

\[
\text { SUMM } 1209 \text { MAE } 12026.2 \text { CDRE TUBE }
\]

\end{aligned}
\]

Figure B-7. - Mass spectrometer scans for sample 12026-2, run 2.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12028-1
2. Weight: 96.8 grams
3. Sample Description (from original description)

Rock type: Core tube 2012
Physical appearance: Fines from lower end of core tube; material lighter in color than that from upper end of core tube
4. Sample History

Return container: Core tube - D-ALSRC
Schematic processing diagram: D-ALSRC—Bioprep-GAL glove box
Storage container sequence: Core tube-Wasserburg container
Processing comments: The core tube was opened in Bioprep and the material removed for analysis. The sample was sealed in the Wasserburg container 2 hours after the core tube was opened.

Control sample numbers: 1201 and 1202
5. Total Carbon Analysis Results: Not available
6. Organic Analysis Results

Maximum total ionization: \(8.1 \times 10^{4}\)
Total ionization: \(2.5 \times 10^{6}\)
Estimated organic content (total of indigenous and contamination): 1.0 ppm
7. Remarks

The summary plot indicates, in later scans, the evolution of organic material that may be indigenous. The spectra are characterized by what may be unsaturated hydrocarbon peaks. High evolution of CO and \(\mathrm{CO}_{2}\) was noted. Sample 12028-1 is the most promising sample analyzed. Some m/e 64 evolved ( \(\mathrm{S}_{2}\) or \(\mathrm{SO}_{2}\) ). The first 10 scans indicate that terrestrial contamination is present; however, later scans in the summary plot show the evolution of material that may be indigenous. The mass spectrometer scans for sample 12028-1 are shown in figure B-8.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12032-1
2. Weight: 310.6 grams
3. Sample Description (from original description)

Rock type: D
Physical appearance: Fines from documented sample bag 4-D; medium dark gray, poorly sorted; some angular fragments up to 4 millimeters in length
4. Sample History

Return container: Teflon bag
Schematic processing diagram: Teflon bag \(\longrightarrow\) Bioprep-GAL glove box
Storage container sequence: Teflon bag \(\longrightarrow\) stainless steel can-Wasserburg container

Processing comments: The material was stored in the Teflon bag inside a stainless steel can until the bag was opened. The sample for organic analysis was taken within 30 minutes after the bag was opened and 15 days after the D-ALSRC was opened in Bioprep.

Control sample number: 1201
5. Total Carbon Analysis Results

Run no. Sample weight, g Carbon content. ppm
1
0. 1519
\(20 \doteq 10\)
2
. 3813
6. Organic Analysis Results

Maximum total ionization: \(1.0 \times 10^{5}\)
Total ionization: \(2.3 \times 10^{6}\)
Estimated organic content (total of indigenous and contamination): 0.1 ppm
7. Remarks

As with the other sample of fines from a documented bag (sample 12042-1), this sample is extremely low in organic content. The low total C content correlates with the low organic content.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12033-1
2. Weight: 322.7 milligrams
3. Sample Description (from original description)

Rock type: D
Physical appearance: Fines from documented sample bag 5-D; described as lightcolored volcanic ash
4. Sample History

Return container: Teflon bag
Schematic processing diagram: Teflon bag \(\longrightarrow\) Bioprep \(\longrightarrow\) GAL glove box
Storage container sequence: Teflon bag \(\longrightarrow\) stainless steel can \(\longrightarrow\) Wasserburg container

Processing comments: The processing comments are the same as for sample 12032-1.

Control sample number: 1201
5. Total Carbon Analysis Results
\begin{tabular}{ccc} 
Run no. & Sample weight, g & Carbon content, ppm \\
1 & 0.1997 & \(20 \pm 5\) \\
2 & .6014 & \(23 \pm 2\) \\
3 & .1254 & \(80 \pm 10\)
\end{tabular}
6. Organic Analysis Results: Not available
7. Remarks

The sample for the third run was provided by the Physical-Chemical Test Laboratory (PCTL) and was transferred to the GAL in a plastic vial, which explains the high C content. An organic analysis was not performed on this sample.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12034-2 2. Weight: 153 grams
3. Sample Description (from original description)

Rock type: Breccia (C)
Physical appearance: Medium light-gray matrix of fine-grained material; includes crystal fragments and fragments of a number of rock types; documented sample bag 6-D
4. Sample History

Return container: Documented sample bag (Teflon)
Schematic processing diagram: D-ALSRC—Bioprep-GAL glove box
Storage container sequence: Documented sample bag-stainless steel can \(\longrightarrow\) Wasserburg container

Processing comments: The rock was exposed in the cabinet for approximately 6 hours before the organic sample was taken. The rock was not touched by rubber gloves, only by Teflon and stainless steel.

Control sample numbers: 1201 and 1202
5. Total Carbon Analysis Results
Run no. Sample weight, g Carbon content, ppm
1
0.2446
\(65 \pm 12\)
6. Organic Analysis Results

Maximum total ionization: \(1.7 \times 10^{4}\)
Total ionization: \(1.1 \times 10^{6}\)
Estimated organic content (total of indigenous and contamination): 0.4 ppm
7. Remarks

The sample was contaminated slightly with Teflon (scan 80, fig. B-9). Other organic material was very low in quantity and was possibly contamination from other sources. The mass spectrometer scans for sample 12034-2 are shown in figure B-9.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12040-2 2. Weight: 319 grams
3. Sample Description (from original description)

Rock type: B
Physical appearance: Light gray with slight greenish tinge caused by olivine; no vesicles but a number of vugs; high olivine content
4. Sample History

Return container: D-ALSRC
Schematic processing diagram: D-ALSRC \(\longrightarrow\) Bioprep \(\longrightarrow\) GAL glove box
Storage container sequence: D-ALSRC \(\longrightarrow\) stainless steel can \(\longrightarrow\) Wasserburg container

Processing comments: The rock was exposed to the Bioprep cabinet atmosphere for approximately 6 hours before the organic sample was taken. The material sampled was from the interior surface of the freshly broken rock.

Control sample numbers: 1201 and 1202
5. Total Carbon Analysis Results

Run no. Sample weight, g Carbon content. ppm
1
0.2245
\(45 \doteq 15\)
6. Organic Analysis Results

Maximum total ionization: \(2.9 \times 10^{4}\)
Total ionization: \(1.2 \times 10^{6}\)
Estimated organic content (total of indigenous and contamination): 0.1 ppm
7. Remarks

Sample 12040-2 shows lower CO and \(\mathrm{CO}_{2}\) evolution and a very small amount of organic material, which is possibly a nylon or dust-particle-type contamination. The mass spectrometer scans for sample 12040-2 are shown in figure B-10.

Figure B-10. - Mass spectrometer scans for sample 12040-2.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12042-1
2. Weight: 225.6 grams
3. Sample Description (from original description)

Rock type: D
Physical appearance: Fines from documented sample bag 12-D
4. Sample History

Return container: Teflon bag
Schematic processing diagram: Teflon bag-Bioprep-GAL glove box
Storage container sequence: Teflon bag \(\longrightarrow\) stainless steel can-Wasserburg container

Processing comments: The processing comments are the same as for sample 12032-1.

Control sample number: None
5. Total Carbon Analysis Results

Run no. Sample weight, g Carbon content, ppm
1
0. 2452
\(125 \doteq 5\)
2
. 3409
\(132 \pm 5\)
6. Organic Analysis Results

Maximum total ionization: \(2.5 \times 10^{4}\)
Total ionization: \(1.2 \times 10^{6}\)
Estimated organic content (total of indigenous and contamination): 0.1 ppm
7. Remarks

Sample 12042-1 was extremely clean and showed considerably less material than did the fines from other sources. The \(\mathrm{CO}_{2}\) evolution, however, was comparable to other samples of fines.

\section*{TOTAL CARIBON AND ORGANIC ANALYSIS}
1. Sample Number: 12044-2, -1
2. Weight: \(\frac{145.4 \text { milligrams }}{\text { (sample } 12044-2)}\)
3. Sample Description (from original description)

Rock type: A
Physical appearance: Fine-grained crystalline rock in documented sample bag
4. Sample History

Return container: Teflon bag
Schematic processing diagram: Teflon bag—Bioprep—GAL glove box
Storage container sequence: Teflon bag—stainless steel can—Wasserburg container

Processing comments: The rock was removed from the bag and stored in a stainless steel can. The sample was taken for organic analysis by chipping the larger rock 15 days after the D-ALSRC was opened. Both the interior and exterior surfaces of the rock were analyzed.

Control sample number: 1201
5. Total Carbon Analysis Results

Run no. Sample weight, g Carbon content, ppm
1
0.3071
\(44 \pm 5\)
6. Organic Analysis Results

Maximum total ionization: \(1.0 \times 10^{5}\)
Total ionization: \(1.8 \times 10^{6}\)
Estimated organic content (total of indigenous and contamination): 0.2 ppm
7. Remarks

Samples 12044-2 and 12044-1 have the same probable contaminants as the other samples. As in previous runs, this rock sample showed less organic content than did the fines. Considerable \(\mathrm{CO}_{2}\) evolution was noted.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12052-4
2. Weight: 3119 grams (three pieces)
3. Sample Description (from original description)

Rock type: B
Physical appearance: Coarse-grained rock; some pyroxene crystals 810 millimeters long by 0.5 millimeter wide; high in ilmenite; radially oriented feldspar in patches; rock apparently heavily shocked; olivine basalt
4. Sample History

Return container: D-ALSRC
Schematic processing diagram: D-ALSRC—Bioprep-GAL glove box
Storage container sequence: D-ALSRC——stainless steel can-Wasserburg container

Processing comments: The rock was exposed to the Bioprep cabinet atmosphere approximately 6 hours before the organic sample was taken. The rock chip was broken and subdivided in the GAL glove box. The chip was approximately 20-percent exterior surface.

Control sample numbers: 1201 and 1202
5. Total Carbon Analysis Results
\begin{tabular}{ccc} 
Run no. & Sample weight, g & Carbon content, ppm \\
1 & 0.3326 & \(34 \pm 10\) \\

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12057-1
2. Weight: 0.5 gram
3. Sample Description (from original description)

Rock type: D
Physical appearance: Medium dark chip; may be a breccia
4. Sample History

Return container: D-ALSRC
Schematic processing diagram: D-ALSRC——Bioprep-Wasserburg container
Storage container sequence: D-ALSRC—Wasserburg container
Processing comments: The chip was removed from the box and sealed in the Wasserburg container 1 hour after the box was punctured for gas analysis. The lid had been off the box for only 2 minutes when the sample for carbon and organic analysis was collected.

Control sample numbers: 1201 and 1202
5. Total Carbon Analysis Results

Run no. Sample weight, g Carbon content, ppm
1
0.2194
\(120 \pm 10\)
6. Organic Analysis Results

Maximum total ionization: \(2.5 \times 10^{4}\)
Total ionization: \(1.2 \times 10^{6}\)
Estimated organic content (total of indigenous and contamination): 0.3 ppm
7. Remarks

Considerable CO and \(\mathrm{CO}_{2}\) and some \(\mathrm{m} / \mathrm{e} 64\) was noted. Almost no other material evolved. The mass spectrometer scans for sample 12057-1 are shown in figure \(\mathrm{B}-12\).

Figure B-12. - Mass spectrometer scans for sample 12057-1.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12059-1
2. Weight: 460.2 milligrams
3. Sample Description (from original description)

Rock type: D
Physical appearance: Fines and some small (10 to 15 milligram) chips
4. Sample History

Return container: D-ALSRC and documented sample bags
Schematic processing diagram: D-ALSRC——Bioprep-GAL glove box
Storage container sequence: D-ALSRC—stainless steel can—Wasserburg container

Processing comments: Material was dusted from the loose rocks and the Teflon sample bags into a stainless steel pan. The material was exposed to cabinet atmosphere for 25 hours before sampling for carbon analysis. The rocks were dusted by a gas stream blown from a polyethylene squeeze bottle.

Control sample numbers: 1201 and 1202
5. Total Carbon Analysis Results

Run no. Sample weight, g Carbon content, ppm
1
0. 1270
\(240 \pm 25\)
\(2 \quad .1336 \quad 120 \doteq 15\)
6. Organic Analysis Results

Maximum total ionization: \(1.9 \times 10^{6}\)
Total ionization: \(4.2 \times 10^{7}\)
Estimated organic content (total of indigenous and contamination): \(>2 \mathrm{ppm}\)
7. Remarks

Sample 12059-1 was contaminated severely compared to the other samples that were run. Scan 40 (fig. B-13) is representative of one type of contaminant; Teflon (scan 92) is the other contaminant. The excess contamination was probably caused by flaking of the Teflon bag, blowing N from the polyethylene bottle, and extra handling. The second run contained a chip mixed in with the fines. The high \(C\) content correlates with the higher organic content.

Figure B-13. - Mass spectrometer scans for sample 12059-1.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}
1. Sample Number: 12063
2. Weight: 2416 grams
3. Sample Description (from original description)

Rock type: A
Physical appearance: Light to medium gray with many darker spots caused by glass in small pits and shadowed vugs
4. Sample History

Return container: Tote bag
Schematic processing diagram: Tote bag \(\longrightarrow \mathrm{LM} \longrightarrow \mathrm{CM} \longrightarrow \mathrm{CRA} \longrightarrow \mathrm{PCTL}\)
Storage container sequence: Tote bag-CDR's gloved (?) hand-aluminum foil-copper-flanged stainless steel container

Processing comments: Sample 12063 was subjected to considerable handling and to the LM, CM, and terrestrial atmospheres. The copper-flanged container was cleaned by ultrasonication in benzene/methanol and by vacuum bakeout. The rock chip was taken in the PCTL and sterilized at \(160^{\circ} \mathrm{C}\).

Control sample number: None
5. Total Carbon Analysis Results

Run no. Sample weight, g Carbon content, ppm
1
0.2755
\(35 \pm 10\)
6. Organic Analysis Results: Not available

\section*{7. Remarks}

Excessive handling and exposure to atmosphere apparently has not increased the contamination, which could be explained if the sample were an interior surface.

\section*{TOTAL CARBON AND ORGANIC ANALYSIS}

The remarks are the same as for sample 12063.

\section*{APPENDIXC}

\section*{ORGANIC-MONITOR DATA SHEETS}

\section*{OTTAWA-SAND ORGANIC MONITORS}

Baked Ottawa sand was used to monitor the background levels in the various LRL sample-processing cabinetry. Standard Ottawa sand is sieved to pass 20 to 30 mesh, which calculates to an average spherical grain volume of \(5.2 \times 10^{-4}\) cubic centimeters and an average grain weight of 1.4 milligrams. Thus, the surface area was approximately \(22.6 \mathrm{~cm}^{2} / \mathrm{g}\) of sand.

Two batches of sand were prepared: one to monitor the F201 vacuum system and one to monitor the nitrogen processing in the Bioprep cabinet. The F201 OM was prepared by washing the sand with water and firing it at \(1000^{\circ} \mathrm{C}\) overnight. The Bioprep OM was prepared at ARC by washing the reagent-grade Ottawa sand with acid and firing it at \(1000^{\circ} \mathrm{C}\) for 30 hours. Samples of both batches were analyzed using benzene/ methanol extraction and high-resolution mass spectrometry at UCB and pyrolysis mass spectrometry at the LRL; the results of these analyses served as the control data. Approximately 200 grams of both the control and the exposed portions of each of these monitors were available for distribution to the Group D Principal Investigators.

The F201 OM control (Teflon bagged) yielded \(3.08 \mu \mathrm{~g} / \mathrm{g}\) of extractables, which calculated to \(0.136 \mu \mathrm{~g} / \mathrm{cm}^{2}\); the Bioprep OM control yielded \(2.32 \mu \mathrm{~g} / \mathrm{g}\) of extractables, which calculated to \(0.103 \mu \mathrm{~g} / \mathrm{cm}^{2}\). A second extraction of this sample yielded only background. The high-resolution mass-spectral data indicated mainly hydrocarbons from \(\mathrm{C}_{4}\) to \(\mathrm{C}_{25}\) of as much as \(6^{\circ}\) of unsaturation and octoil (dioctyl phthalate). Oxygenated species were found in minor amounts (cyclic ketones, low-weight carboxylic acids, and an oxygenated compound with the composition \(\mathrm{C}_{23} \mathrm{H}_{32}{ }^{\mathrm{O}} 2\), after loss of one \(\mathrm{C}_{10} \mathrm{H}_{20}\) group).

The results of the pyrolysis mass-spectrometer analyses for the control samples are given in appendix B. The mass spectrometer scans for the Ottawa-sand organic monitors are shown in figure \(\mathrm{C}-1\).

Figure C-1. - Mass spectrometer scans for Ottawa-sand organic monitors.

\section*{ORGANIC MONITOR 1007-2}

Organic monitor 1007-2 was cleaned by the ALSRC-1574 cleaning procedure together with the contents of ALSRC 1009 (the S-ALSRC). The sample weighed 49.96 grams and yielded a benzene/methanol (3:1) extract residue of 0.2 milligram. Assuming a York-mesh surface area of \(60 \mathrm{~cm}^{2} / \mathrm{g}\), the residue was equivalent to \(0.05 \mu \mathrm{~g} / \mathrm{cm}^{2}\) of extractable organics. The gas chromatogram (GC) showed only trace peaks above the background level, and the high-resolution mass-spectral data (one of the scans is illustrated in fig. \(\mathrm{C}-2\) ) indicated the presence of a more diverse suite of organic compounds. The major constituents were octoil ( \(\mathrm{C} / \mathrm{H}_{3}\) plot, fig. C-2), which was substantiated by the GC run, and hydrocarbons ranging from \(\mathrm{C}_{4}\) to \(\mathrm{C}_{12}\). Traces of carboxylic acids to \(\mathrm{C}_{8}\) were found.

Figure C-2. - Mass spectrometer scans for organic monitor 1007-2.

\section*{ORGANIC MONITOR 1007-4}

Organic monitor 1007-4 was cleaned by the ALSRC-1574 cleaning procedure together with the ALSRC 1009 box, the temperature sensor, and the seal protectors. The sample weighed 40.92 grams and yielded a benzene/methanol (3: 1) extract residue of 0.25 milligram, which was equivalent to \(0.12 \mu \mathrm{~g} / \mathrm{cm}^{2}\). This high value was the result of some fine \(\mathrm{AlO}_{2}\) passing through the filtering grit. The GC trace showed no peaks, and the high-resolution mass-spectral data indicated only trace hydrocarbons that were barely above the solvent background.

The mass spectrometer scans for OM 1007-4 are shown in figure C-3.

Figure C-3.- Mass spectrometer scans for organic monitor 1007-4.

\section*{ORGANIC MONITOR 1008}

Organic monitor 1008 was cleaned by the ALSRC-1574 cleaning procedure together with the contents of ALSRC 1008 (the D-ALSRC) and then baked under vacuum conditions at \(160^{\circ} \mathrm{C}\) in the LRL F250 conditioning chamber. The sample of York mesh weighed 11.02 grams, and the benzene/methanol (3:1) extract residue was 0.05 milligram above the solvent background, which corresponded to \(0.08 \mu \mathrm{~g} / \mathrm{cm}^{2}\) of extractables. No GC trace was run, but the high-resolution mass-spectral data indicated carboxylic acids to approximately \(\mathrm{C}_{12}\) as the major components, with octoil and hydrocarbons as minor constituents.

The mass spectrometer scans for OM 1008 are shown in figure C-4.

Figure C-4.- Mass spectrometer scans for organic monitor 1008.

Organic monitor 1009 was cleaned by the ALSRC-1574 cleaning procedure together with the ALSRC 1009 contents and then baked under vacuum conditions at \(160^{\circ} \mathrm{C}\) with ALSRC 1009 in the LRL F250 conditioning chamber. The sample weighed 12.31 grams, and the benzene/methanol (3:1) extract residue was 0.06 milligram above the solvent background, which corresponded to \(0.08 \mu \mathrm{~g} / \mathrm{cm}^{2}\) of extractables. The GC trace indicated no peaks at the highest attenuation. The high-resolution mass-spectral data indicated mainly a suite of hydrocarbons from \(\mathrm{C}_{4}\) to \(\mathrm{C}_{16}\) of varying degrees of unsaturation and octoil. Oxygenated compounds also were present in significant amounts; for example, cyclohexanone, cyclopentanone, butyric acid, and tetrahydronaphthol.

The mass spectrometer scans for OM 1009 are shown in figure C-5.

Figure C-5. - Mass spectrometer scans for organic monitor 1009.

\section*{EXTRACTION SOLVENTS}

One liter each of benzene and methanol (both nanograde purity) were evaporated. This amount represents a tenfold larger quantity of solvent than was used for the extraction. The GC traces were run and showed no detectable peaks. The benzene background consisted mainly of hydrocarbons ranging from \(\mathrm{C}_{4}\) to \(\mathrm{C}_{18}\) of varying degrees of unsaturation and minor amounts of octoil and carboxylic acids from \(\mathrm{C}_{4}\) to \(\mathrm{C}_{15}\). The methanol background consisted mainly of dissolved inorganics, traces of hydrocarbons, and low-weight carboxylic acids.

The high-resolution mass-spectral data for methanol are shown in figure C-6 and for benzene in figure C-7.

Figure C-6. - High-resolution massspectral data for methanol.

Figure C-7. - High-resolution mass-spectral data for benzene.

ALSRC 1008 LID

The ALSRC 1008 lid sample was the residue from the cleaning solution used to clean the LESC and GASC lid hardware that was stowed in ALSRC 1008 during the Apollo 12 mission. The cleaning procedure consisted of washing both the inside and the outside of the lid of the prime organic container. The extractable portion of the solution weighed 5 . 0 milligrams after solvent evaporation. The GC of the extract (the heptane solubles) is shown in figure C-8. The high-resolution mass-spectral data indicated dioctyladipate and octoil as the major components. The presence of dioctyladipate was substantiated by the series of peaks in figure C-8. Hydrocarbons and the free acids \(\mathrm{C}_{4}\), \(C_{5}, C_{12}\), and \(C_{13}\) were found as minor components.

The mass spectrometer scans for the ALSRC 1008 lid are shown in figure C-9.

Figure C-8. - Data plot of ALSRC 1008 lid wash.

Figure C-9. - Mass spectrometer scans for ALSRC 1008 lid.

\section*{APPENDIX D}

\section*{PHOTOGRAPHIC INDICES}

The photographs of the Apoll.o 12 lunar samples have been indexed in the following ways: (1) a log of all photographs taken, (2) an index of photographs by sample number and an index of samples by photograph number, and (3) a cross-reference of samples with the lunar-surface collection location, photographs, and chronological sequence.

\section*{PHOTOGRAPHIC LOG}

Effective use of 70-millimeter photographs taken on the Apollo 12 EVA requires extensive information about the camera parameters and camera location and orientation at the time each photograph was taken. The amount of such data that are being derived for each picture is too extensive to include concisely in one listing. The log has therefore been divided into two versions. The first version, which is presented here, is designed primarily to support general photographic interpretation. Two complete photographic listings are presented in this version. The first listing (table D-I) is a listing of all the photographs in chronological sequence and is useful for understanding the context of each photograph taken during the EVA traverses. The second listing (table D-II) is a sequential listing of photographs from each individual magazine and is useful for locating information about any given photograph. The second version, which is still in preparation, contains detailed geometric information required for precise mensuration of surface features from the photographs.

The two cameras used for primary lunar-surface scientific and engineering documentation during the Apollo 12 lunar stay were 70 -millimeter Hasselblad cameras with automatic electric-film-advance and shutter-cocking mechanisms. Each camera was equipped with a specially designed f/5.6 Biogon lens and a reseau plate at the film plane that imprinted a five-by-five array of crosses on each photograph at the time of exposure. Although the focus settings on each camera were continuously variable, three detents were provided in the focusing ring to provide a finite number of repeatable focus settings. The conventional set of detents was available at 0.5 f-stop intervals on the adjusting ring for the iris. Shutter speeds of 1 to \(1 / 500\) th second were available; however, with few exceptions, the exposure setting used on the lunar surface was \(1 / 250\) th second. Both cameras were calibrated prior to launch for photometric and photogrammetric data reduction.

During the first EVA, color film was used in magazines Y and V . Magazines X and Z , used during the second EVA, contained black-and-white film.

Three main types of analyses were used to prepare this part of the log: (1) comparison of images on the Hasselblad photographs with those on Lunar Orbiter photographs, (2) comparison of photographs of geological sample sites with those taken of returned samples in the LRL, and (3) comparison of image data with data transmitted verbally during the EVA.

An explanation of the boxheads used in tables D-I and D-II is given in the following paragraphs.

PHOTO: The last six digits of the official NASA number assigned to each photograph shortly after processing. Each number is prefixed by "AS12." The last four digits of each number are unique, but numbers are sequential within a given film magazine only. The numbers do not represent a chronological order because two magazines were used simultaneously.

MAG: The letter designation assigned to the film magazine.
SEQ: The chronological sequence in which each picture was taken, as nearly as can be determined.

REMARKS: Comments about each picture that may refer to objects in the picture, to something the crew said about their reasons for taking the picture, to some unusual aspect of the subject of the picture, to number designations of samples appearing in the picture, or to the inferred reason for taking the picture. Descriptions of the photographic surveys and definitions of acronyms and abbreviations referred to in this column are given in the following two sections.

GET: Ground elapsed time, which is the time since lift-off, in hours and minutes, when the picture was taken, as nearly as can be determined from voice transmissions.

BY: Crewmember who took the picture. Discussion by the crew of subject matter in several pictures was sufficient to identify the photographer.

DIST and AZLM: Distance and azimuth of camera stations from the center of the LM (clockwise from north). These were determined by identifying features on both Lunar Orbiter and Apollo 12 EVA photographs and by computing photograph location using the standard surveying technique of resection. The distances given are not the same as those given in some of the remarks, which simply refer to the shortest distance to any part of the LM.

AZ: Azimuth (clockwise from north) along which the camera was aimed. This was also determined during resection. When the photograph was part of a panorama, the azimuths of other photographs in the panorama were measured from photomosaics of the panorama.

\section*{Photographic Surveys}

Three basic types of photographic surveys were made by the Apollo 12 astronauts specifically for lunar-surface interpretation: (1) panoramas, (2) sample surveys, and (3) a polarimetric survey. These surveys are described in the following paragraphs.

Panoramas. - A total of 23 panoramas was taken during the Apollo 12 lunar stay. These include partial panoramas from inside the LM taken through both windows, complete \(360^{\circ}\) panoramas taken from the surface at intervals throughout the traverse, and
partial panoramas frequently taken in pairs for stereoscopic average of large features of particular interest.

Panoramas taken from the LM windows are useful because of their high vantage point, even though their azimuthal field of view is little more than \(180^{\circ}\). The view from the windows of the area in the vicinity of the LM is not often occulted by local topography, as photographs from the surface are. This lack of occultation permits detailed examination of continuous views of the surface.

Complete panoramas are taken to record as much lunar-surface detail as possible with a lunar-surface-based camera. Comparison of the appearance of surface features in pictures taken from orbit and in pictures taken from the lunar surface is useful in geological interpretation. Panoramic photographs also augment crew discussions of the area. When joined together as mosaics, the panoramas provide accurate map control data in the form of horizontal angles. This can be done analytically, with high precision, from measurements of glass-plate reproductions of the photographs, or graphically, with moderate precision, by measuring the mosaics themselves. Complete panoramas are more useful than broken or partial panoramas in the sense that they provide an immediate check of error accumulation in measuring horizontal angles, and because lunar directions can be determined accurately and independently of any other data from the locations of the image of the sun and the image of the astronaut's shadow. This was one of the reasons that the crew was requested to take pictures into the sun, even though poor picture quality was anticipated.

Partial panoramas produce some of the same data as complete panoramas at a considerable saving of film. They are useful for photographic documentation of large features of geological interest. When two partial panoramas are taken of the same feature from slightly different vantage points, pairs of pictures from the adjacent panoramas can be viewed stereoscopically, and precise photogrammetric measurements of the feature can be made.

Sample surveys. - The sample surveys were taken to illustrate the in situ characteristics of samples of lunar material returned to earth and to aid identification of sampling locations along the traverse. Most of the sample pictures were taken in stereoscopic pairs to aid in interpretation and photogrammetric measurement of the sample area. Many contain a self-righting wand, or gnomon, which serves as a scale, a vertical reference, and, by casting a shadow, a lunar azimuth indicator.

Polarimetric survey. - A polarimetric survey was made only once, early in the second EVA, with a polarizing filter attached to the camera. This type of survey was made to study the polarizing properties of lunar material. A series of pictures of the same area was taken from different locations and with different orientations of the polarizing filter.

\section*{Glossary of Acronyms and Abbreviations}

\section*{Used in the Photographic Log}
\begin{tabular}{|c|c|}
\hline ALSEP & Apollo lunar-surface experiments package \\
\hline AUX & Auxiliary \\
\hline BOT & Bottom or underside \\
\hline CAM & Camera \\
\hline CDR & Commander (Astronaut Charles C. Conrad) \\
\hline CENT STA & Central station of ALSEP \\
\hline CH & Changed \\
\hline COMP A & One of two compartments on the Surveyor III spacecraft containing electronic components \\
\hline CONT & Contingency sample \\
\hline CSM & Command and service module \\
\hline CT & Core tube \\
\hline CTR & Crater \\
\hline DN SUN & Camera was aimed directly away from the sun when the picture was taken. \\
\hline DPS & Descent propulsion system, i.e., the exhaust cone under the descent stage of the LM \\
\hline E & East \\
\hline EVA & Extravehicular activity, i.e., astronaut activity outside the LM \\
\hline FLD SPL & A number designation on sample bags carried by the astronauts. One or more samples in the same bag were designated by the same 'field' sample number. \\
\hline IDENT & Identification \\
\hline IN & Inch \\
\hline L & Left \\
\hline LESC & Lunar-environment sample container \\
\hline LM & Lunar module \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline LMP & Lunar module pilot (Astronaut Alan Bean) \\
\hline LRL SPL & A number given in the LRL to a sample of lunar material. More than one LRL sample may have the same field sample number. \\
\hline LTR & Lighter \\
\hline MAG & Film magazine \\
\hline N & North \\
\hline OMNI & Omnidirectional antenna. The Surveyor III spacecraft has two such antennas, designated "Omni A" and "Omni B." \\
\hline PSE & Passive-seismic-experiment instrument \\
\hline R & Right \\
\hline RADVS & Radar altimeter and Doppler velocity sensor - part of the automatic landing system on the Surveyor W spacecraft \\
\hline RK & Rock \\
\hline RTG & Radioisotope thermoelectric generator - the power source for ALSEP instruments \\
\hline RTND & Returned \\
\hline S & South \\
\hline SEQ BAY & Scientific equipment bay - a storage compartment on the descent stage of the LM \\
\hline SMSS & Soil mechanics surface sampler - the scoop on the Surveyor III spacecraft \\
\hline SPL & Sample (of lunar material) \\
\hline SWC & Solar-wind-composition measuring device \\
\hline SWE & Solar-wind-experiment instrument \\
\hline TRN & Trench \\
\hline W & West \\
\hline X-SUN & Camera was aimed across the direction of illumination. \\

\section*{PHOTOGRAPHIC INDICES BY SAMPLE AND PHOTOGRAPH NUMBERS}

The index of photographs by sample number (table D-III) is designed to help locate photographs that show part or all of any specific Apollo 12 lunar sample. Conversely, the index of samples by photograph number (table D-IV) is designed to help locate photographs that are not listed by sample number. The latter index is more complete and contains more explanatory information.

\section*{SAMPLE CROSS-REFERENCE}

The third index (table D-V) is a cross-reference of all samples collected during the EVA traverses with (1) the tentative lunar-surface locations, (2) the lunar-surface photographs in which the samples are shown, and (3) the chronological sequence (in ground-elapsed time) in which the samples were collected. The tentative identification of the samples is based on a combination of the astronauts' descriptions and a correlation of the sample characteristics as seen in the NASA and the surface photographs. Samples indicated in the first column of table D-V as "(?)" have notbeen identified; however, where the sample number is given with the " (?)," the reference to an actual sample is strongly suggested. Further study of the surface photographs may permit additional identification and orientation of the samples.

\section*{APPENDIXE \\ MAJOR UPDATES AS OF JULY 31, 1970}

The data contained in this appendix are considered to be of major significance in the preliminary description of the Apollo 12 lunar samples. The data are both new data and corrections and modifications of earlier data. No attempt has been made to update the main part of this document completely; rather, this appendix is included to correct only the most serious problems. The following five changes have been made to this document.
1. The photomicrographs of thin sections (figs. A-64 to A-95) have been expanded to include at least one photomicrograph of each sample that was sectioned.
2. Many photographs of the rocks have been replaced with more recent photographs that show greater detail.
3. Tables D-I and D-II have been recast.
4. The LRL photographic indices (tables D-III and D-IV) have been updated.
5. The cross-reference among the sample numbers, the lunar-surface photograph numbers, and the mission transcript (table \(D-V\) ) has been updated.

The first part of this appendix is a list of errata that references the number of the page that is affected by more recent data. The second part is an Apollo 12 rock classification. The last two parts consist of a current list of the various samples that have lunar orientation or location data associated with them and a supplementary list of the sample locations and orientations.

\section*{ERRATA}

Pages 1, 43, Samples 12010, 12013, 12034, and 12073 are microbreccias. and 57:

Pages 75, 76, Samples 12008, 12009, and 12015 are modally and texturally the and 86: same; slightly devitrified glass with approximately 10 percent olivine phenocrysts (some skeletal) and approximately 5 percent small skeletal trains of olivine.

Pages 47 and 82: Sample 12013 is considerably more complex texturally than was previously thought. It consists of a mixture of at least four types of matrices and a wide variety of fragments. This sample is not a 'late-stage differentiate."

Sample 12003-36, a polished thin section that contains three fragments of the coarse fines from this sample, was studied. The first fragment is a 5 -millimeter porphyritic olivine basalt. The second fragment is a 4 -millimeter breccia. The third fragment is a recrystallized anorthosite, perhaps containing a new mineral. The recrystallized anorthosite consists of a meshlike intergrowth of plagioclase microlites, including minor amounts of olivine, opaques, and the unidentified mineral.

The unidentified mineral (found by A. Ried of MSC) is a single, highly reflecting grain 0.2 by 0.1 millimeter. Other physical properties are high relief and medium birefringence, and the mineral is apparently pleochroic in yellow-green and brown. The outer margin of the mineral appears to be in reaction relation with the plagioclase groundmass.

Page 117: Sample 12035 is not a troctolite. It is a granular basalt containing less than 10 percent olivine and several percent of cristobalite.

\section*{APOLLO 12 ROCK CLASSIFICATION}

As of July 31, 1970, thin sections are available for 36 of the 45 returned rocks. Also, there are thin sections of five large chips from sample 12057, which consists of a variety of rock fragments. Study of these thin sections provided the data for the following textural classification. The photographs of one unsectioned sample were clear encugh to enable that sample to be classified.

This classification is not intended to be final. First, there are 9 rocks (approximately one-quarter of the collection) that have not been sectioned. Second, mineralogical and chemical data on all rocks are far from complete. A complete classification of any rocks demands a melding of textural, chemical, and mineralogical information.

The Apollo 12 rocks are broadly classified as crystalline rocks and microbreccias. The crystalline rocks are further classified as variolitic basalts, porphyritic olivine basalts, olivine vitrophyre, granular basalts and gabbros, ophitic and subophitic basalts, and porphyritic ophitic basalts. The granular basalts are similar to the Apollo 11 type B rocks, and the ophitic and subophitic basalts are similar to the Apollo 11 type A rocks.

In reading the following descriptions, the reader should refer to the photomicrographs of the various thin sections (figs. A-64 to A-95). An asterisk next to a sample number indicates that a thin section of that sample is not presently available.

\section*{Variolitic Basalts \\ Samples 12004, 12019, 12052, 12053, and 12065}

The pyroxene in these rocks displays well-developed variolitic texture; that is, random pyroxene phenocrysts as long as 3 millimeters in a matrix consisting of a feathery intergrowth of pyroxene and plagioclase crystals. These rocks typically contain euhedral to rounded olivine phenocrysts and platelike ilmenite. A generalized mode of these rocks is as follows.
\begin{tabular}{lr} 
Plagioclase & 15 to 25 percent \\
Pyroxene & 55 to 70 percent \\
Olivine & 5 to 15 percent \\
Opaques & 5 to 10 percent \\
Silica & 0 to 2 percent
\end{tabular}

Samples exist that fall between the variolitic basalts and the porphyritic olivine basalts.

> Porphyritic Olivine Basalts and Peridotite Samples \(12002,12012,12014,12018,12020,12022\), 12045,12075 , and 12076

The olivine in these rocks forms euhedral to rounded phenocrysts as long as 1.5 millimeters across. The remainder of the rocks are similar to the variolitic basalts. Pyroxene phenocrysts are present. The matrix consists of lath-shaped plagioclase crystals in a more-or-less ophitic relation to matrix pyroxene prisms. The opaque phase forms as equant grains. In addition, platelike ilmenite crystals are found in some samples (especially well developed in samples 12022 and 12045). Unlike the variolitic rocks, matrix pyroxene does not form feathery masses. A generalized mode for these rocks is as follows.
\begin{tabular}{lr} 
Plagioclase & 10 to 20 percent \\
Pyroxene & 35 to 50 percent \\
Olivine & 25 to 40 percent \\
Opaques & 5 to 15 percent
\end{tabular}

Samples exist that fall between the variolitic basalts and the porphyritic olivine basalts.

\section*{Olivine Vitrophyre \\ Samples 12008, 12009, and 12015*}

The matrix of these rocks consists of black glass and small ( 0.01 millimeter) crystals of silicates and opaques. Olivine phenocrysts form as euhedral, subhedral, and skeletal crystals as long as 1 millimeter across. A second generation of olivine forms stringers of optically continuous skeletal crystals that are 0.05 millimeter across. Modally, olivine comprises approximately 20 percent of these rocks, about equally divided between the phenocrysts and the stringers.

Granular Basalts and Gabbros
Samples l2035\#, l2036\#, 12039\#, 12040\#, l2044, 12056, 12057-4, 12057-9\#, and 12064

The pyroxene and olivine in these rocks form subhedral crystals. The pyroxenes are 0.5 to 1 millimeter in size in the basalts and range to 5 millimeters in the gabbros. The gabbros are indicated by a "\#." Pyrox-ferrite forms as separate crystals in at least one rock (12039). Plagioclase, opaques, and cristobalite form as anhedral crystals. In some rocks, tridymite forms as lathlike crystals as long as 1.5 millimeters. In most of these rocks, the pyroxene and olivine form with many pyroxene-pyroxene and pyroxene-olivine contacts, and plagioclase fills the interstices. This is interpreted as a cumulate texture. A generalized mode of these rocks is as follows.
\begin{tabular}{lr} 
Plagioclase & 20 to 40 percent \\
Pyroxene & 45 to 55 percent \\
Olivine & 5 to 20 percent \\
Opaques & 5 to 15 percent \\
Silica & 0 to 10 percent
\end{tabular}

Samples exist that fall between the granular basalts and the ophitic basalts. These rocks are similar to the Apollo 11 type B rocks.

Ophitic and Subophitic Basalts
Samples 12006, 12038, 12046, 12047, 12051, 12057-6, 12057-7S, 12062, and 12063S

The plagioclase laths forming the ophitic texture in these rocks are as long as 2 millimeters. Ilmenite forms as platelike crystals that are slightly shorter than the plagioclase laths. Pyroxene forms as equant crystals and cristobalite fills the
interstices. The samples marked with an ' S ' ' in the heading of this section have less well-defined ophitic texture and are considered subophitic. A generalized mode for these rocks is as follows.
\begin{tabular}{lr} 
Plagioclase & 30 to 45 percent \\
Pyroxene & 40 to 55 percent \\
Olivine & 0 to 5 percent \\
Opaques & 5 to 10 percent \\
Silica & 0 to 5 percent
\end{tabular}

Samples exist that fall between the ophitic basalts and the granular basalts. These rocks are similar to the Apollo 11 type A rocks.

> Porphyritic Ophitic Basalts
> Samples 12017, 12021, and 12031*

The most distinguishing feature of these rocks is the pyroxene phenocrysts that are as long as 2.5 centimeters. The matrix of these rocks is similar to that of the ophitic or subophitic basalts. In sample 12017, there are small ( 0.5 millimeter) patches of matrix that are similar to the matrix of the variolitic basalts. A generalized mode for these rocks is as follows.
\begin{tabular}{lc} 
Plagioclase & 30 to 35 percent \\
Pyroxene & 55 to 60 percent \\
Opaques & 5 to 7 percent \\
Silica & 3 to 5 percent \\
Microbreccias \\
Samples 12010, 12013, \(12034,12057-11\), and 12073
\end{tabular}

The microbreccias are a shock-lithified mixture of glass, mineral, and rock fragments. Glass spherules are commonly found. Fragments of breccia are found as components of these samples. These rocks are similar to the Apollo 11 type C rocks. Sample 12013 has many special features that will not be described here.

\section*{LOCATION AND ORIENTATION OF SAMPLES}

The location of lunar rocks is determined by the Field Geology Team (FGT) on the basis of two types of primary information: the transcript of the astronauts' comments during the EVA traverses and the LRL and lunar-surface photographs.

The orientation of the lunar samples is derived from one or more of the following experiments.
1. Lunar-surface photographs - As described in the sample location and sample identification and orientation sections of this document, the lunar-surface photographs show the orientation of the sample when it was picked up by the astronaut. This orientation experiment is performed by the FGT and is the only orientation experiment that provides north-south-east-west data. The other experiments yield only "top" and "bottom" data.
2. Pit counting - Pit counting is performed by F. Horz at MSC. A 'top" is obtained that is an integration of the entire lifetime of the rock on the lunar surface.
3. Gamma-ray counting - Gamma-ray counting is performed by E. Schonfeld at MSC and by R. W. Perkins at the Battelle Memorial Institute, Richland, Washington. Three types of "top" may be obtained from this work. Each type is derived by counting a different isotope and is thus an integration over a length of time that is dependent on the half life of the counted isotope. The three types are as follows.
\begin{tabular}{lc} 
Isotope & Approximate time of integration \\
\(\mathrm{Al}^{26}\) & \(10^{6}\) years \\
\(\mathrm{Na}^{22}\) & 10 years \\
\(\mathrm{Co}^{56}\) & 2 months
\end{tabular}

Those samples that have had orientation work performed on them are listed in table E-I. Most of the location results are given in figure 3 and in table D-V. Most of the orientation data of the FGT are given in the sample location section of this document; the rest of this information will be published later.

TABLE E-I. - ORIENTATION WORK PERFORMED ON THE APOLLO 12 LUNAR SAMPLES - Concluded

\section*{SUPPLEMENTARY LIST OF APOLLO 12 SAMPLE LOCATIONS AND ORIENTATIONS}

The following sections describe the Apollo 12 lunar samples that have been identified and oriented with various degrees of confidence between January 31 and July 31, 1970. The current status of all samples is summarized in table E-II.

All rock identifications from the selected sample are considered to be tentative, based solely on an LRL correlation of sample shapes, sizes, and shadow characteristics with photographs of rocks taken on the lunar surface by the astronauts. The status is considered tentative because, during the selected-sample traverse (the first EVA), the individual samples were not bagged and no specific indication was made of which samples were photographed before collection. Most lunar-surface photographs taken of rocks during this traverse show several fragments, any one or several (or none) of which may have been picked up. There was not a one-to-one relation between the lunarsurface photographs and the samples. Furthermore, no postsampling photographs were taken to indicate which rocks had been picked up.

Confidence in the identification and orientation of rocks in the documented sample is higher than for those in the selected sample for several reasons. Many of the samples were put into prenumbered bags indicating the locations of specific samples. Samples were, for the most part, photographed on the lunar surface together with a tripod gnomon, which, in addition to showing scale on a vertical-seeking weighted bar, pointed out the particular rock to be picked up.

Sample 12006
See the discussion for sample 12020.

\section*{Sample 12007}

Sample 12007 has not been recognized in surface photographs; however, the small, angular, apparently freshly fractured piece of rock may have been taken from the large mound. At 04:22:10 \(\xi\). e.t., the LMP made a comment about chipping off a fragment of a larger rock. The lack of surface pits in sample 12007 may be because this sample was embedded in the large mound.

Sample 12008
Sample 12008 has been tentatively identified on the southeast side of the large mound in Hasselblad photographs AS12-46-6831 and AS12-46-6832 (fig. E-1). The rock is seen on the side of the mound near the left edge of the photograph in figure E-l. Sample 12008 is shown in figure E-2 in the LRL with an approximate reconstruction of the lunar lighting.

Figure E-2.- Approximate lunar orientation of sample 12008 in the LRL.

\section*{Sample 12010}

Sample 12010 has been tentatively identified in Hasselblad photo-
graph AS12-46-6835 (fig. E-3). This photograph was taken near the rim of Middle Crescent Crater. Figure E-4 shows sample 12010 in the LRL with an approximate reconstruction of the lunar lighting. The reconstructed orientation can be correlated most nearly with LRL photographs S-69-62309 and S-69-62310.

Figure E-3. - Enlargement of a portion of Hasselblad photograph AS12-46-6835 showing the tentative identification of sample 12010.

Figure E-4. - Approximate lunar orientation of sample 12010 in the LRL as correlater with Hasselblad photograph Aß12-46-6835.

\section*{Sample 12013}

Sample 12013 is tentatively identified in Hasselblad photograph AS12-46-6833 as the right-hand fragment in a group of three. This photograph was taken near or on the rim of Middle Crescent Crater. Sample 12013 is shown in figure E-5 before it was picked up. Sample 12013 is shown in figure E-6 in the LRL with an approximate reconstruction of the lunar lighting. The lunar orientation can be correlated most nearly with LRL photograph S-69-63360. In the Has selblad photograph, the sample can be seen on the rim of a small crater from which it may have been recently ejected along with the other fragments in the field of view. The fragment lying in the center of the group of three shown in figure E-5 has been identified tentatively as sample 12019.

Figure E-5. - Enlargement of a portion of Hasselblad photograph AS12-46-6833 showing the tentative identification of samples 12013 and 12019 near the rim of Middle Crescent Crater.

Figure E-6. - Approximate lunar orientation of sample 12013 in the LRL. (Note that a slice has been removed for thin sections.)

\section*{Sample 12014}

Sample 12014 is tentatively identified in Hasselblad photograph AS12-47-6940, taken by the LMP on the return trip to the LM from Middle Crescent Crater. Figure E-7 shows sample 12014 on the lunar surface before it was collected. Figure E-8 shows sample 12014 in the LRL in an approximate lunar orientation without a reconstruction of the details of lunar lighting.

Figure E-7. - Photograph showing tentative identification of sample 12014 before it was picked up (AS12-47-6940).

Figure E-8. - Approximate lunar orientation of sample 12014 in the LRL without reconstructed lunar lighting (NASA-S-69-63353).

\section*{Sample 12015}

Sample 12015 has not been recognized in any lunar-surface photograph; however, a comment made by the CDR at 04:22:17 g. e.t. suggests that he picked up a rock that had a "dent" in it. Sample 12015 does have a large, single, nearly spherical cavity on one side. The location of sampling was on the rim of Middle Crescent Crater.

\section*{Sample 12016}

Sample 12016 is tentatively identified in Hasselblad photograph AS12-47-6939, taken on the rim of Middle Crescent Crater by the LMP. Figure E-9, an enlargement of part of the Hasselblad photograph, shows sample 12016 half embedded in the ejecta on the rim of a 2 -meter-diameter crater. Figure E-10 is an approximate reconstruction of the lunar orientation using an LRL model of sample 12016. It is interesting to note that approximately half of sample 12016 appears to be buried by other ejecta from the small crater in a manner similar to the burial of documented sample 12051.

Figure E-9. - Enlargement of a portion of Hasselblad photograph AS12-47-6939 showing the tentative identification of sample 12016 embedded in the rim of a 2 -meterdiameter crater.

Figure E-10. - Photograph of an LRL model of sample 12016 showing the approximate lunar orientation and lighting. The fine details of the surface of the rock are lost on the model. The holes are bubbles formed when the model was made.

\section*{Sample 12017}

Sample 12017 has not been identified in any lunar-surface photograph; however, it is the only rock in the selected sample that had a significant coating of black glass. It is probable that sample 12017 came from the vicinity of the small mound that was the starting point for the selected-sample traverse. Although the sample was not specifically photographed and its lunar orientation at the time of sampling is unknown, it seems likely that the glassy side was up and exposed on the lunar surface so that it attracted
attention and elicited the following comment from the LMP (04:22:02 g.e.t.): ''Hey, here's a rock they 'll be glad to see in Houston. "

Sample 12019
Sample 12019 is tentatively identified in Hasselblad photograph AS12-46-6833 as the center fragment in a group of three resting on the rim of a small secondary crater. The photograph was taken on or near the rim of Middle Crescent Crater; the exact location is not known because the lunar horizon is not shown in the photograph. Figure E-5 is an enlargement of part of Hasselblad photograph AS12-46-6833 and shows sample 12019 before it was picked up. In the same field of view, sample 12013 is also tentatively identified. Figure \(\mathrm{E}-11\) shows an approximate reconstruction of the lunar orientation of sample 12019 in the LRL.

Figure E-11. - Approximate lunar orientation of sample 12019 in the LRL as correlated with Hasselblad photograph AS12-46-6833.

\section*{Sample 12020}

Sample 12020 has not been identified in the lunar-surface photographs; however, the sample is one of two rocks likely to be the 'grinning' rock mentioned by the CDR at 04:22:25 g.e.t. on the return trip to the LM from Middle Crescent Crater during the selected-sample traverse. The other possible contender for the 'grinning'" rock is sample 12006. Samples 12020 and 12006 both have vugs and vesicles that, at the proper lunar orientation and lighting, could have faces. Sample 12006 is shown in figure E-12 in the LRL in an orientation that includes a face. Figure E-13 shows sample 12020 in the LRL held in such a way that the shadows cast by the vugs and fractures produce a face.

Figure E-12. - Photograph of sample 12006 at an angle in which the vugs suggest a face, possibly the "grinning" rock sampled at 04:22:25 g.e.t. (NASA-S-69-61912).

Figure E-13. - Photograph of sample 12020 held in an orientation such that the vugs and fractures suggest a face, possibly the 'grinning' rock.

Sample 12046
Sample 12046 is from the documented sample and was one of three fragments collected on the north rim of Block Crater and put into bag 15-D. Sample 12046 is tentatively identified with moderate assurance in Hasselblad photographs AS12-48-7148, AS12-48-7149, and AS12-48-7150. Figure E-14 is an enlargement of a portion of Hasselblad photograph AS12-48-7149 that shows samples 12046 and 12047 before they were picked up. Figure E-15 shows sample 12046 in the LRL with an approximate reconstruction of lunar lighting.

Figure E-14. - Enlargement of a portion of Hasselblad photograph AS12-48-7149 showing samples 12046 and 12047 before they were picked up and put into bag 15-D. Sample 12045, also included in bag \(15-\mathrm{D}\), has not been identified in the lunar-surface photograph.

Figure E-15. - Approximate lunar orientation of sample 12046 in the LRL.```
